To sum up, the State now owns the value of all development rights in land. A buyer of land who gets permission to develop will (subject to exceptions) have to pay a development charge to the State. It follows that he should not pay a development charge to the landowner as well as to the State by paying him more than the land is worth for its existing use. If the landowner has lost the development value of his land he may receive a compensation payment from the State. A person who buys land above existing use value and who fails to obtain planning permission for further development will be out of pocket on the deal. Most compulsory purchases—for example, by local authorities or others with statutory powers of compulsory acquisition—are, broadly speaking, to be at existing use value.

The provisions of the Act and the various regulations made under it are complicated, and many points of difficulty which will arise may later come before the courts for authoritative interpretation. In a summary within the limitation of this page it is only possible to deal with broad general principles. For the individual case, the best course for those who seek to claim compensation or who are in doubt about their position is to use the services of a qualified surveyor or other person professionally experienced in the valuation of land for the purpose of making their claims.

National Health Service

TERMS AND CONDITIONS OF SERVICE OF HOSPITAL MEDICAL AND DENTAL STAFF (ENGLAND AND WALES)

1. Consultants (Whole-time)

(a) Main Scale for Consultants, including Dental Consultants

- (1) Consultants appointed at age 32 or over (subject to (3) below):

£1,700 × £125–£2,075 × £150–£2,375 × £125–£2,750 per annum.

- (2) Consultants appointed at age 31 or earlier shall start at £1,550 or £1,400 respectively.

- (3) Consultants first appointed after age 32:

the board shall have discretion to fix the starting salary at any of the four next incremental points in the scale,

- (i) by reason of age, special experience, and qualifications, or

- (ii) by reason of age alone, where seniority has been lost because of service with H.M. Forces,

providing that the starting salary shall in no case be higher than the consultant would receive on age alone.

(b) Special Distinction Awards

Where a special distinction award is granted, the value attaching to it (£2,500, £1,500, or £500 per annum) will be paid as an element of remuneration additional to the main scale and will be superannuable.

2. Other Senior Officers (Whole-time)

(a) *Senior Hospital Medical Officers*—senior officers performing clinical duties who are not of consultant status but are not registrars; and

(b) *Senior Hospital Dental Officers*—senior officers performing clinical dental teaching duties in dental hospitals or departments who are not of consultant status but are not registrars:

£1,300 (at age 32) × £50–£1,750 per annum,

the position on this scale to be determined by age (subject to paragraph 12 (b) below).

(c) *Medical Superintendents and Deputy Medical Superintendents*—Medical superintendents and deputies will be paid a salary consisting of—

- (i) for that fraction of their time given to clinical work:

the same fraction of the whole-time salary of a consultant or senior hospital medical officer according to their grading,

- plus (ii) for that fraction of their time given to administrative work

the same fraction of the appropriate rate for hospital administrative staff.

Where, however, a whole-time officer is engaged almost wholly in clinical work and gives only a small proportion of time to administrative duties, his appropriate clinical remuneration shall not be affected.

3. Registrar Grades (including Dental) (Whole-time)

(a) *Junior Registrar*: posts obtained normally not less than one year after registration as a medical or dental practitioner and held normally for one year only:

£670 per annum.

(b) *Registrar*: posts obtained normally not less than two years after registration as a medical or dental practitioner and held normally for two years:

£775 per annum in the first year;

£890 per annum in the second and any subsequent years.

(c) *Senior Registrar*: posts obtained normally not less than four years after registration as a medical or dental practitioner and held normally for three years:

£1,000 per annum in the first year;

£1,100 per annum in the second year;

£1,200 per annum in the third year;

£1,300 per annum in any subsequent years.

NOTES: As each grade of post demands a distinct level of ability and experience, holders of registrar posts shall not proceed from one grade to another by automatic promotion. A registrar in a lower grade will be considered on merit, along with other applicants, for a vacancy in a higher grade.

A Senior Registrar subsequently appointed to a Registrar post will be paid the higher salary appropriate to the Registrar grade (i.e., £890 per annum) whilst he holds the post in that grade.

4. Other Grades (Whole-time)

(a) House Officer (including Dental):

£350 per annum for the first post held;

£400 per annum for the second post held;

£450 per annum for the third and any subsequent post held;

with, in each case, a deduction at the rate of £100 per annum in respect of board and lodging and other services provided. Each post shall be tenable for six months.

The Minister will be prepared to authorize, in exceptional circumstances, salaries up to £50 per annum higher than the standard rates specified above where a post cannot be filled otherwise.

(b) *Junior Hospital Medical Officers*—officers who have held house appointments but who are not registrars, and who have less responsibility than other hospital officers of non-consultant status:

£700 (for an officer appointed not less than two years after registration as a medical practitioner) × £50–£1,000 per annum.

5. Part-time Appointments

(a) Part-time Consultant Appointments

The board shall assess in terms of hours per week what is the average amount of time required by an average practitioner to perform the duties attaching to the post. In assessing the average amount of time to perform the duties attached to the post the board shall take into account out-patient clinics, ward rounds, operating sessions, laboratory work, and so on in their hospitals, including occasional visits to outlying hospitals for consultation, diagnosis, or operative work. The board shall also include time given—e.g., as consultant adviser to the board on special branches of the service or by way of "pastoral visits" to outlying hospitals—and time necessarily required in travelling between home or private consulting-room (whichever is the nearer) and the hospital or hospitals served (unless the journey is one which the consultant would undertake irrespective of his work for the board). There shall be excluded from the computation any element of time for emergency calls by consultants to patients in the beds in their charge (except where any exceptionally heavy liability to recurring emergency work of this sort is anticipated), or for committee work, or for the care of private patients in pay-beds or as out-patients. There shall also be excluded time required for domiciliary consultations for which special fees are payable (see paragraph 8).

This aggregate number of hours per week shall be expressed as a number of notional "half-days" per week. The number of notional "half-days" shall be arrived at from the aggregate of hours so assessed, by dividing the total by 3½, the consultant being given the benefit of the marginal overlap, as follows:

No. of hours weekly	No. of notional half-days on which salary will be reckoned
Up to 3½	1
Over 3½ and up to 7	2
" 7 " " " " "	3
" 10½ " " " " " "	4
" 14 " " " " " "	5
" 17½ " " " " " "	6
" 21 " " " " " "	7
" 24½ " " " " " "	8
" 28 " " " " " "	9

B.D.H. two new therapeutic aids

'MYANESIN' Brand ELIXIR

to produce muscular relaxation in spastic conditions 'Myanesin' Elixir is indicated in cases of spastic hemiplegia and paraplegia of the lower limbs due to cerebral haemorrhage, disseminated sclerosis and other upper motor neurone lesions. Striking recovery of voluntary movement with increase of range and improved co-ordination occurred in a series of hemiplegias and cerebral diplegias under 'Myanesin' Elixir medication. The administration of 'Myanesin' Elixir has proved a helpful measure in Parkinsonism.

METHIONINE B.D.H.

for the prevention and treatment of liver damage The power of the amino-acid methionine to correct a deficiency in cases of protein depletion, and to act prophylactically against hepatotoxic agents, led to its trial as a therapeutic measure. Indications for Methionine B.D.H. include the prophylaxis and treatment of hepatic cirrhosis, acute hepatitis, toxic hepatitis and the toxæmias of pregnancy. Methionine may prove a valuable routine prophylactic against hepatorenal damage in pregnancy.

A new treatment for insect bites and stings

The present tendency to ascribe the painful effects of insect bites and stings to the action of histamine has suggested the use of antihistamine therapy in alleviating the symptoms.

Encouraging results have been obtained with 'Anthisan' administered orally. Rapid reduction of the wheal formation and relief of painful symptoms have been experienced in the majority of cases.

Failure to respond to 'Anthisan' is an indication for the substitution of the more powerful antihistaminic, 'Phenergan'.

Some measure of relief can be secured by the local application of 'Anthisan' Cream.

NEO-HEPATEX

An essential link

in the chain of chemical reactions
leading to normal erythropoiesis.

Within six to ten hours of the initial injection a remarkable change occurs in the megaloblastic marrow of pernicious anaemia. The nuclei of the megaloblasts become smaller and in 32 to 72 hours the megaloblastic picture has become normoblastic.

Neo-Hepatex is a non-toxic, highly frac-

tionated, proteolysed extract of liver containing 10 microgrammes of Vitamin B₁₂ per ml., estimated by a combined method of paper chromatography and microbiological assay, using *Lactobacillus lactis* Dorner. Each batch is controlled by clinical tests on hospital cases of true, uncomplicated Addisonian anaemia.

Introducing . . .

ELIXIR METHADON

(preparation of dl-2-dimethylamino 4 :
4 diphenylheptane-5-one hydrochloride)

ELIXIR METHADON (SMITH) is a palatable preparation containing as its active ingredient 2.5 mgm. per fluid drachm of Methadon, the high potency synthetic analgesic. Methadon has proved effective in relieving a wide variety of painful conditions and administration as elixir has definite advantages.

DESCRIPTIVE LEAFLET ON REQUEST

Elixir Methadon (Smith) is available in 4-oz. and 16-oz. bottles and is exempt from purchase tax. It is within the regulations of the Dangerous Drugs Acts.

FEMERGIN

ERGOTAMINE TARTRATE B.P.

for the specific treatment of

THE MIGRAINE ATTACK

Relief from the excruciating pain is obtained in approximately 90 per cent. of attacks of true migraine by the subcutaneous injection of $\frac{1}{2}$ -1 ml. Femergin, given as early as possible in the attack. In mild cases 2-4 tablets taken sublingually may prove sufficient to abort the attack.

SANDOZ PRODUCTS LIMITED

13-1 Wigmore Street, London, W.1

The part-time salary shall be the following proportion of the whole-time salary appropriate to the consultant concerned:

$$\frac{\text{number of half-days}}{11} + \frac{\text{one-quarter of number of half-days}}{11}$$

or

$$\frac{\text{number of half-days}}{11} + \frac{\text{one-quarter of } (11 - \text{number of half-days})}{11}$$

whichever is the less, together with the same proportion of the value of any distinction award held by him, the total being subject to the maximum referred to in (d) below.

(b) Part-time Appointments as Senior Hospital Medical Officer or Senior Hospital Dental Officer

The above formula for arriving at part-time salaries shall be applied to all part-time appointments as Senior Hospital Medical Officer or Senior Hospital Dental Officer.

(c) Part-time Registrars

In the case of part-time appointments in the registrar grades, the number of notional half-days on which the salary is reckoned shall be arrived at as in (a) above. The part-time salary shall be the following proportion of the whole-time salary appropriate to the registrar concerned:

$$\frac{\text{number of half-days}}{11}$$

subject to the maximum referred to in (d) below.

(d) Maximum Remuneration for Part-time Appointments

The maximum remuneration for part-time appointments under (a) and (b) above shall be $9\frac{1}{2}$ elevenths of the whole-time remuneration (including the value of any distinction award) appropriate to the officer concerned; and for part-time appointments under (c) above shall be 9 elevenths of the whole-time salary appropriate to the officer concerned.

Where a practitioner holds part-time appointments with more than one board or hospital management committee which together do not constitute a whole-time appointment, this maximum shall apply to the aggregate remuneration from all the boards or committees concerned.

This maximum shall not, however, include payments made in respect of exceptional consultations performed for a board with whom the practitioner is not in contract, payments made in respect of work as locumtenent, and payments for domiciliary consultations, referred to in paragraph 8.

(e) In special circumstances a board, with the Minister's consent in each case, shall have discretion to offer a higher rate of part-time remuneration than that normally applicable.

6. Exceptional Consultations

Consultants who have no contract with the board, but who are called in exceptionally to hospitals or clinics for a special visit (e.g., because of their unusual experience or interest) shall be paid at the rate of 5 guineas per visit (including any operative work, etc.). This, however, shall not apply to retired consultants who hold honorary (unpaid) appointments in respect of exceptional calls on their services of this kind (see paragraph 15).

A general practitioner not on the staff of a hospital but called in exceptionally to render a specific service in emergency shall be paid at the rate of £2 per visit, unless the service rendered falls within his terms of service under Part IV of the Act.

7. Locum tenens Arrangements

Payment at the rate of 5 guineas per half-day shall be made to a locum engaged by a board during a consultant's temporary absence when it is impossible to arrange for his work to be adequately performed by other members of the board's staff within the terms of their contracts of service.

A locum engaged by a board or hospital management committee during the temporary absence in similar circumstances of a Senior Hospital Medical Officer, a Senior Hospital Dental Officer, or a general practitioner holding an appointment of the kind described in paragraph 10 (b) shall be paid at the rate of 3½ guineas per notional half-day.

8. Domiciliary Consultations

(a) No additional payment shall be made for domiciliary consultation by whole-time officers. Part-time officers shall be paid on the following basis:

Fee for consultation, 4 guineas, with an additional fee of

(1) 2 guineas where any operative procedure other than obstetric is undertaken or where the officer uses his own electrocardiograph or portable x-ray apparatus;

(2) 4 guineas for an obstetric operation;

the additional fee of 2 guineas or 4 guineas to be payable only in respect of each patient for the current illness.

(b) Boards shall make payments, additional to the fees set out above and to the normal travelling and subsistence expenses, of 1 guinea for a journey to a place over 20 and up to 40 road miles distant, 2 guineas for a journey to a place over 40 and up to 60 road miles distant, and so on, with an additional guinea for every 20 miles.

(c) The maximum remuneration under this head (excluding travelling and subsistence allowances, additional mileage payment, and fees for the use of the officer's own apparatus) shall be 200 guineas in any quarter or 800 guineas in any year, whichever the officer prefers.

9. Clinical Consultants engaged in Teaching of Medical or Dental Students

1. (a) Holders of whole-time clinical posts in medical or dental schools, and

(b) Teachers (including part-time clinical professors or heads of university clinical departments) who devote a large portion of their time to university work,

shall hold honorary (unpaid) appointments with the appropriate hospital board or boards, but, like other consultants, shall receive from the boards payment of appropriate expenses for hospital work, and shall also be eligible for distinction awards. An officer under (b) above will receive that proportion of the value of a distinction award which corresponds to the proportion of the whole-time salary attaching to his teaching post.

2. Part-time Clinical Teaching Posts

Consultants performing teaching duties concomitantly with, or separately from, their clinical work shall be remunerated by hospital boards like other consultants (including distinction awards and expenses) in addition to any remuneration they may receive from the university or school in recognition of their teaching duties.

10. General Practitioners on the Staffs of Hospitals (Part-time)

(a) *General Practitioner Hospitals (Cottage Hospitals) Other than Maternity Hospitals*

Remuneration in respect of services rendered other than those paid for by the Executive Council: the hospital management committee shall create a staff fund by making a payment of £25 per annum for each bed (other than private pay-beds and maternity beds) occupied on the average in the hospital, the fund to be shared among the general practitioner staff as they may themselves determine.

(b) *Part-time Medical Officers at Convalescent Homes, General Practitioner Maternity Hospitals, or Other Types of Hospital Where no Other Rate is Appropriate*

£175 per annum per weekly "notional" "half-day" up to a maximum of £1,575 per annum, the "half-days" being assessed as in paragraph 5 (a). Where, however, the number of "notional" hours weekly is 2 or less the remuneration shall be determined as follows:

1 hour or less	£50 per annum
over 1 hour but not more than 2 hours					£100 per annum

11. General Dental Practitioners employed at Hospitals

£150 per annum per weekly "half-day" up to a maximum of £1,350 per annum, the "half-days" being assessed as in paragraph 5 (a).

12. Determination of Salaries Payable from July 5, 1948**(a) Consultants**

Assuming there has been no break in service (other than one occasioned by war service or national service on call-up), the salary payable from July 5, 1948, shall be the salary which the officer would have been receiving on that date had the above system of remuneration been in operation since the date on which he first accepted a hospital staff appointment with full clinical responsibility. In the case of consultants who first accepted such an appointment after age 32, boards, in determining what their starting salaries at that time would have been, shall exercise their discretion as they would have exercised it had they been the appointing authority (see paragraph 1 (a) (3)).

(b) Senior Hospital Medical Officers and Senior Hospital Dental Officers

Boards or hospital management committees shall have discretion to decide at which point in the salary scale existing staff should start, provided that the starting salary shall in no case be higher than that which the officer would receive were his position on the scale determined by age alone.

(c) Medical Superintendents and Deputy Medical Superintendents

The initial salary shall be the sum of the appropriate fraction of the whole-time clinical salary as determined under paragraphs 2 (c) and 12 (a) or (b) and the appropriate fraction as determined under paragraph 2 (c) of the minimum of the relevant administrative salary scale.

(d) Junior Hospital Medical Officers

Existing staff who immediately before July 5, 1948, were receiving less than the minimum remuneration for the grade shall start at the minimum of the salary scale; and those who were receiving more than the minimum shall enter the scale at the salary they were receiving immediately before July 5, 1948, rounded off, at the discretion of the board or management committee, to the next incremental point in the new scale.

(e) Transferred Officers

Officers who were transferred under Section 68 of the National Health Service Act, 1946, and who immediately before July 5, 1948, were receiving salaries better than those now introduced, shall be entitled to retain their previous salary scale and conditions of service (including emoluments) on a personal basis for as long as they remain in the same appointment or another appointment of the same or greater responsibility as the one they held at the appointed day, but otherwise they shall conform to the new rates of remuneration and conditions of service on taking up a new appointment or on promotion: provided that travelling and subsistence allowances as set out in paragraph 19 shall be adopted for all officers irrespective of the allowances for which they may have been eligible before transfer.

13. Incremental Dates

In the case of officers holding appointments at July 4, 1948, the incremental date shall be July 5; in the case of new appointments or promotions, the date on which the new post was entered into; except that transferred officers who exercise an option under paragraph 12 (e) shall, so long as they retain their previous salary scale and conditions of service, also retain their previous incremental dates.

14. Private Practice and Retention of Fees**1. Private Practice**

A whole-time officer shall not be entitled to undertake private practice. For this purpose "private practice" includes general practice under Part IV of the Act (except in respect of members of the hospital staff), and the diagnosis or treatment of patients by private arrangement under Section 5 (2) of the Act; but does not include work of the kind referred to in Category II below.

2. Retention of Fees

(i) Where services such as the rendering of medical reports on patients who are under observation, or treatment, or the

examination, diagnosis, and rendering of reports on persons referred to hospitals for these purposes only, are not within the scope of the hospital and specialist services provided under Section 3 of the Act, they may be made available at hospitals or by members of hospital medical staffs on payment of appropriate charges, but only where in the opinion of the board or committee their provision would not interfere with other hospital activities or with the proper discharge of the hospital duties of the officer concerned. Where in the provision of such services hospital laboratory or radiological facilities are used, the charges made shall represent two elements: (a) payment for professional services and (b) payment of hospital costs. Where hospital laboratory or radiological facilities are not required, no charge shall be made for the use of hospital premises, payment being in respect of professional services only.

Whether the practitioner providing such services is a whole-time or a part-time officer, all charges in respect of professional services shall be retained by him or remitted to him by the board or committee according as the money is received by the practitioner himself or by the board or committee.

Where hospital laboratory or radiological facilities are used one-third of whatever payment is made for the item of service provided shall be remitted to or retained by the board or committee, in respect of hospital costs.

(ii) Where services of the kind referred to above are within the scope of the hospital and specialist services provided under Section 3 of the Act, they shall be performed by members of hospital medical staffs as part of their hospital duties and without charge.

The following Schedule illustrates the principles governing the distinction between work of this kind which is within the scope of the hospital service, and work of this kind which is not within the scope of the service and for which, therefore, charges will be made.

SCHEDULE**Category I: Work which is within the scope of the Hospital and Specialist Services provided under Section 3 of the Act**

(a) Examination and diagnosis and the furnishing of any report reasonably required in connexion therewith on a person referred to the hospital and specialist service for this purpose from a medical source for a second medical opinion. Examples are:

(i) examination and report on a person referred by a general practitioner;

(ii) examination and report on a person referred by a medical board of the Ministry of Pensions;

(iii) examination and report on a person referred under the National Insurance (Industrial Injuries) Act, 1946, by a regional medical officer of the Ministry of National Insurance or by a medical board or medical appeal tribunal for the purposes of that Act;

(iv) examination and report on a person referred by a medical referee appointed under the Workmen's Compensation Act, 1925, or under a scheme certified under Section 31 of that Act;

(v) examination and report on a person referred by a medical recruiting board of the Ministry of Labour and National Service;

(vi) examination and report on a person referred by a medical interviewing committee set up by the Ministry of Health to advise disablement resettlement officers of the Ministry of Labour and National Service on the working capacity of disabled persons;

(vii) examinations and reports on members of H.M. Forces or their families referred by medical officers of His Majesty's Forces who are treating them;

(viii) examinations and reports on patients referred (in connexion with diagnosis or treatment) by medical officers of local education authorities or local health authorities. (N.B.—Reports required on employees by these authorities in their capacity as employers are included in Category II (a) (iv) below.)

(b) X-ray examination of any person resorting to or referred to a mass radiography unit, and the furnishing of a report, if required, of the result of such examination.

(c) Examinations and the furnishing of written reports on the mental or physical condition of offenders referred by courts under Sections 24 and 26 of the Criminal Justice Act, 1948.

(d) The furnishing of a report to a patient who is under observation or treatment at the hospital at the time when the report is asked for, or with his consent to an interested third party, when the information required can be given without a special examination of the patient by reference to hospital records or from knowledge acquired in the course of attendance on the patient. (N.B.—If a

special examination of the patient is required, or the information requested cannot be given readily from knowledge of the case, the work would fall within Category II below.)

The following are examples of reports or certificates which it would normally be possible to provide without special examination of the patient

(i) progress reports required by the Ministry of Pensions on a pensioner who is under hospital observation or treatment,

(ii) reports required by employers (including Government Departments and local authorities) on employees who are under observation or treatment (e.g., reports required in connexion with sick leave, superannuation, or retirement questions, etc.) (Employees who are not under observation or treatment are referred to under Category I (a) (iv) below)

(iii) the "first" certificate of the cremation certificates required by relatives, where death took place in hospital (N.B.—The "first" certificate would normally be given by the practitioner who had attended the patient in hospital, and would not involve a special examination. For the "second" certificates see (a) (x) of Category II below)

Category II: Work which is not within the scope of the Hospital and Specialist Services provided under Section 3 of the Act

(a) The following are examples of examinations, reports, etc., which, when they do not fulfil any of the conditions referred to in paragraphs (a), (b), (c), and (d) in Category I above, are outside the scope of the hospital and specialist service

(i) any report on a patient not under observation or treatment at the hospital at the time the report is asked for, or any report involving special examination of the patient other than those in (a), (b), (c) of Category I,

(ii) examinations and reports for prospective emigrants—including x-ray examinations and blood tests,

(iii) examinations and reports on candidates for admission to training colleges for teachers,

(iv) examinations and reports required by employers (including Government Departments and local authorities) on employees or prospective employees (except employees or prospective employees of a board or hospital management committee at the hospital concerned) (N.B.—These would, therefore, normally be in Category II where the employees or prospective employees were not under hospital observation or treatment but were referred to hospitals or to members of hospital medical staffs specially for the purpose of examination and report)

(v) examinations and reports on private citizens in connexion with legal actions,

(vi) examinations and reports for coroners,

(vii) examinations required for life insurance purposes,

(viii) certificates required under the Blind Persons' Act,

(ix) attendance at court hearings as medical witnesses,

(x) the "second" certificate of the cremation certificates required by relatives, where the deceased had been under hospital observation or treatment (N.B.—The "second" certificate would not be given by the practitioner who had been attending the patient. For the "first" certificate see (d) (iii) of Category I)

(b) Other work in this category includes

(i) lectures given by members of hospital medical staffs to nurses, etc., or to the lay public,

(ii) services performed by members of hospital medical staffs for Government Departments as members of medical boards,

(iii) general practitioner services given by a hospital medical officer under Part IV of the Act to members of the hospital staff who are on his "list."

15. Retiring Age

When an officer reaches age 65 his regular contract shall come to an end, provided that.

(a) the board or hospital management committee may, with his consent, extend his contract of service (or offer a modified contract) for one year or any less period, and so from time to time until age 70, or

(b) in the case of a consultant the board may allow him an honorary contract as indicated in paragraph 6

These ages shall be reduced by five years in respect of practitioners who are "mental health officers" as defined in the National Health Service (Superannuation) Regulations, 1947

16. Tenure of Post

Where a consultant considers that his appointment is being unfairly terminated by a board, he shall be entitled to send a

full statement of the facts to the Minister, who will obtain the written views of the board concerned and place the case before a professional committee (consisting of representatives of the Ministry and representatives of the profession, under the chairmanship of the Chief Medical Officer) for their advice. The committee shall have discretion to interview both parties if they think fit. In the light of their advice the Minister may confirm the termination of services, or direct reinstatement, or arrange some third solution agreeable to the parties concerned, such as re-employment in a different post. This procedure shall be completed before the board's decision to terminate the consultant's services is carried into effect.

It is understood that where a local change of organization in the hospital and specialist services involves displacement or serious disturbance of a part-time consultant's services, the board recognizes that it has a moral obligation to render the greatest possible assistance to the consultant to obtain comparable work in another hospital

17. Residential Appointments

The above rates of remuneration are inclusive. Where an officer is provided with board and lodging or accommodation by the hospital (i.e., the officer's main hospital) a charge shall be fixed by the hospital management committee (or board of governors) equal to the value of the services provided, except that the charge for house officers shall be at a fixed rate of £100 per annum (see paragraph 4 (a)). In the case of officers appointed by a regional hospital board, the charge shall be fixed by the hospital management committee subject to the approval of the board.

18. Leave

(a) Annual Holiday Leave

Officers in receipt of salaries of less than £1,000. At the rate of four calendar weeks per annum (in addition to statutory and general national holidays or days in lieu)

Officers in receipt of salaries of £1,000 or more. At the rate of six calendar weeks per annum (in addition to statutory and other general national holidays or days in lieu)

In the case of officers holding part-time appointments, leave entitlement shall be based not on the actual salary but on the corresponding whole time salary rate

Absence for such purposes as attendance at court shall not be taken into account for the purposes of annual leave

The annual leave year shall run from April 1 to March 31, except in the case of house officers, whose leave period shall correspond to the period of tenure of the post. New entrants to the Service shall be entitled to annual leave proportionate to the completed months of service during the year of entry and thereafter on the normal scale, provided that, except in the case of house officers, no leave shall be taken until an officer has completed six months' service. An officer who enters the Service during the second half of the leave year shall be allowed to carry forward the leave to which he is entitled (on a proportionate basis) during that leave year and take it during the following year.

(b) Compassionate Leave

Special leave with pay shall be granted at the discretion of the appointing authority (i.e., board or management committee as appropriate) in cases of urgent domestic distress (e.g., bereavement). As a normal rule, the period of absence so authorized shall not exceed three days, but, since much may depend on individual circumstances, the authority shall have discretion, on general and humanitarian grounds, to extend the period in cases of special hardship up to a further three days—i.e., up to a maximum of six days in all.

(c) Leave for Volunteers for the Auxiliary Armed Forces

An officer who, with the consent of the appointing authority, volunteers for service with the Territorial and Auxiliary Forces shall be granted, in addition to his annual leave entitlement, one week's paid leave for camp, and shall be free to choose whether the second week should count as unpaid leave (not counting for increment) additional to his normal entitlement, or as part of his normal entitlement of annual leave with pay.

An officer posted to the Territorial Army or other Auxiliary Forces after compulsory whole-time training shall be granted

special leave without pay for the necessary training period, unless he prefers the period of absence to count in whole or in part against his annual leave entitlement. Special leave without pay granted in these circumstances shall count for increment.

(d) "Study" Leave, Conferences, etc.

(i) "Study" leave must be for the purposes of study (including research), teaching, examining, taking examinations, visiting clinics, or attending meetings or conferences of a wholly scientific or clinical character. Where study leave is granted with pay the officer must not undertake any remunerative work without the special permission of the leave-granting authority.

(ii) Subject to these conditions, study leave may be granted on the following basis:

A. For short periods of one or two days, but in exceptional cases up to a maximum of seven days:

1. Without pay or expenses—in the case of officers appointed by a regional hospital board, at the discretion of the board, unless authority has been delegated to the hospital management committee; in other cases at the discretion of the management committee or board of governors.

2. With pay but without expenses—at the discretion of the board unless authority has been delegated to a hospital management committee.

3. With pay and expenses—at the discretion of the board—subject to (iii) below.

B. For periods exceeding seven days but not exceeding thirteen weeks:

1. Without pay or expenses } at the discretion of

2. With pay but without expenses } the board.

3. With pay and expenses—at the discretion of the board, subject to (iii) below;

provided that:

(a) where an officer is employed by more than one board the leave must be approved by all the boards concerned;

(b) where leave with pay is granted for a period in excess of three weeks, half of the excess shall be counted against the officer's annual leave entitlement, the officer being allowed for this purpose to carry forward annual leave not exceeding three weeks in all from the immediately preceding leave year;

(c) not more than one period of paid leave shall be granted to one officer in any one leave year.

C. For periods exceeding 13 weeks:

1. Without pay or expenses—at the discretion of the board, provided that where an officer is employed by more than one board, the leave must be approved by all the boards concerned.

2. With pay but without expenses } to be referred to the

3. With pay and expenses } Ministry for decision.

(iii) Where study leave is granted for the purpose of sitting an examination, no expenses (fees, travelling, or subsistence) will be payable.

(e) Sick Leave

(1) Scale of Allowances

An officer absent from duty owing to illness, injury, or other disability shall be entitled to receive an allowance in accordance with the following scale:

During the first year of service:

One month's full pay and (after completing four months' service) two months' half pay.

During the second year of service:

Two months' full pay and two months' half pay.

During the third year of service:

Three months' full pay and three months' half pay.

During the fourth to sixth years of service:

Four months' full pay and four months' half pay.

During the seventh to tenth years of service:

Five months' full pay and five months' half pay.

After completing 10 years of service:

Six months' full pay and six months' half pay.

The board shall have discretion to extend the application of the foregoing scale in an exceptional case.

(2) Calculation of Allowance

(a) The rate of allowance and the period for which it is to be paid in respect of any period of absence due to illness shall be ascertained by deducting from the period of benefit appropriate to the officer's service on the first day of his absence the aggregate of the periods of absence due to illness during the twelve months immediately preceding the first day of absence.

(b) For the purpose of ascertaining the appropriate period of benefit under (1) above, all periods of service (without any break of twelve months) under any employing authority from whom hospitals have been transferred, any employing authority constituted under the National Health Service Act, or any local authority, or in the Civil Service or the teaching service, or on war service or on national service (on call up), or in any other service approved by the Minister for the purposes of Regulation 46 (4) of the National Health Service (Superannuation) Regulations, 1947, shall be aggregated.

(c) The allowance made to an officer during absence on sick leave when added to—

(i) the amount of sickness benefit receivable under the National Insurance Act, 1946;

(ii) the amount of injury benefit receivable under the National Insurance (Industrial Injuries) Act, 1946;

(iii) compensation payments under the Workmen's Compensation Acts where the right to compensation arises in respect of an accident sustained before July 5, 1948;

(iv) any element in compensation payments under the Employers' Liability Acts or under Common Law which is attributable to immediate loss of wages; and

(v) any amount received as a treatment allowance from the Ministry of Pensions;

shall not exceed the officer's normal monthly salary, and the sick-leave allowance shall be restricted accordingly where necessary.

(d) The benefits to be taken into account under (c) (i)-(v) above shall be those for the officer's own incapacity, including allowances for adult and child dependants.

(e) Where a married woman has exercised her option not to be insured under the National Insurance Act, no deduction shall be made from her normal sick-leave allowance during ordinary absence on sick leave, as she will not be receiving sickness benefit.

(f) For the purposes of this clause, twenty-six working days shall be deemed to be equivalent to "one month."

(3) Conditions

(a) An officer who is prevented by his illness from reporting for duty shall notify immediately the officer prescribed for this purpose by the employing authority. If his absence continues after the third day he shall submit forthwith a medical certificate as to the nature and probable duration of the illness. Thereafter medical certificates shall be submitted at intervals of seven days or at such longer intervals as in any case may be decided by the employing authority. On his returning to duty the officer shall submit a medical certificate of fitness if required.

(b) An officer entering a hospital or similar institution shall submit a medical certificate on entry and on discharge in substitution for periodical certificates.

(c) A case of a serious character, in which a period of sick leave on full pay in excess of the period of benefit under (1) above would, by relieving anxiety, materially assist a recovery of health, shall receive special consideration by the employing authority.

(d) An allowance shall not be paid in a case of accident due to active participation in sport as a profession nor in a case in which contributory negligence is proved, unless the employing authority by resolution decide otherwise.

(e) A period of absence due to injury sustained by an officer in the actual discharge of his duty and without his own default shall not be recorded for the purposes of this scheme.

(f) An officer who has received an allowance under this scheme in respect of a period of disability and recovers damages in respect of the disability shall advise the employing authority forthwith, and the employing authority may, if they consider it equitable, require the officer to refund a sum equal to the aggregate of the allowances paid to him during the period of disability or such part thereof as is deemed appropriate, but not exceeding the amount of the damages recovered, and in that event the period covered by the sum recovered shall not be recorded for the purposes of this scheme.

(g) The employing authority may at any time require an officer who is unable to perform his duties as a consequence of illness to submit to an examination by a medical practitioner nominated by the authority. Any expense incurred in connection with such examination shall be met by the authority.

(h) The provisions of this scheme shall cease to apply to an officer on the termination of his employment whether by reason of permanent ill-health or infirmity of mind or body or by reason of age, but without prejudice to the right of an officer whose employment is terminated by reason of permanent ill-health or infirmity to receive the period of notice provided by his contract of service.

(i) If it is reported to the employing authority that an officer has failed to observe the conditions of this scheme or has been guilty of conduct prejudicial to his recovery and the authority is satisfied that there is substance in the report, the payment of the allowance shall be suspended until the authority has made a decision thereon, provided that before making a decision the employing authority shall advise the officer of the terms of the report and shall afford him an opportunity of submitting his observations thereon and of appearing, or being represented, before the authority or its appropriate committee. If the employing authority decide that the officer has failed without reasonable excuse to observe the conditions of the scheme or has been guilty of conduct prejudicial to his recovery, then the officer shall forfeit his right to any further payment of allowance in respect of that period of absence.

(4) Contact with a Case of Notifiable Disease

This scheme shall not apply to an officer who is required to absent himself from duty following contact with a case of notifiable disease. In such a case the period of absence shall be regarded as special leave with full pay.

19. Expenses

(a) General

Travelling, subsistence, and other expenses shall be paid to meet actual disbursements of officers engaged in the service of the board and shall not be regarded as a source of emolument or reckoned as such for purposes of pension.

In preparing claims officers shall indicate adequately the nature of the expenses involved, claims shall be submitted normally at intervals of not more than one month, and as soon as possible after the end of the period to which the claim relates.

(b) Travelling Expenses

Travelling expenses shall be paid by the board for any journey in the board's service, provided that

(i) in the case of a whole-time officer, expenses incurred in travelling between his place of residence and the hospital where his principal duties lie shall not be allowed except as indicated in (d) below,

(ii) in the case of a part-time officer, travelling between his private consulting-room or place of residence and any hospital where he is employed, whichever is the less, shall be regarded as a journey in the board's service, provided that no expenses shall be allowed for any such journey, or part of such journey which would have been undertaken by the officer irrespective of his employment with the board,

(iii) expenses incurred in travelling from holiday leave to duty or vice versa shall not be allowed unless the officer was recalled for special reasons,

(iv) taxi or cab fares shall be payable only in cases of urgency or in other cases in which transport is reasonably

required and an adequate public service is not available, but where these conditions are not fulfilled an officer using a taxi or cab shall be entitled to claim the sum he would have been paid had he travelled by public service vehicle,

(v) an officer making an overnight journey by rail and engaging sleeping-car accommodation shall receive the cost, but any subsistence allowance payable to him for that night shall be reduced by one-third.

Rates

(1) Except where a private car is used, the sum paid shall not exceed the amount disbursed—e.g., if the practitioner is entitled to travel first class but in fact takes a third-class ticket he can only claim third-class fare.

(2) First-class fares shall be paid to whole-time officers with salaries of £760 and over, and to part-time officers of corresponding status.

(c) Car Allowances

Officers, whether whole-time or part-time, shall be classified as "regular users" or "casual users" according to whether their annual official regular mileage is estimated to exceed 2,000 miles or not.

All regular users of motor-cars, of whatever horse-power, shall be paid an annual allowance of £52 and 3½d per mile. The annual allowance shall be paid by quarterly instalments in advance. The mileage allowance shall be paid monthly or quarterly. The annual allowance shall continue during absences on annual leave or sick leave or whilst the car is out of use being repaired or overhauled, except that where any one period of non-use exceeds two months the sum of £4 6s 8d shall be deducted for each complete month after the first (e.g., if a car is out of use for 3½ months, £8 13s 4d should be deducted from the allowance).

If at the end of the year it is found that an officer who has been treated as a regular user has not completed 2,000 miles, he shall not be called upon to repay any part of the annual allowance. This does not preclude review and re-classification of any officer at any time where appropriate.

Casual users shall receive no annual allowance, but shall be paid 7½d a mile for the first 3,120 miles a year and 3½d a mile thereafter.

Where a "regular user" has contracts with more than one board which require him to make a claim to more than one board, the board with whom he has his main contract shall be responsible for paying the annual allowance of £52 and for verifying from time to time from the other boards concerned that the officer is still a regular user, all the boards concerned paying 3½d a mile for actual mileage in the claims appropriate to them.

If an officer uses a private motor vehicle in circumstances where travel by a public service would be appropriate, a mileage allowance of 1½d a mile shall be payable irrespective of the type of vehicle.

Where other officers, or members of an employing authority, are conveyed in the same vehicle on the business of the National Health Service, and where fares by a public service would otherwise be payable, an allowance of 4d a mile for each passenger shall be payable.

The "allowance year" for the purpose of car allowance shall be regarded as the year to March 31. In the first year in which an officer is authorized to use his car, a proportionate reduction of the 3,120 miles or adjustment of the annual allowance (as the case may be) shall be made.

In this paragraph and paragraph (b) above, "public service" refers to railways, steamships, omnibuses, and tramways.

(d) Payment of Mileage Allowances to Whole-time Officers for Journeys from Home to the Hospital where Principal Duties lie

(i) Where a whole-time officer travels from his home to the main hospital either before and/or after an official journey, travels direct from his home to the place visited, or returns direct from that place to his home, mileage allowance shall be payable for the whole distance travelled, subject to a maximum based on the return journey from the officer's main hospital to the place visited plus 20 miles.

I hereby accept the appointment mentioned in the letter to me dated from the secretary of the
Regional Hospital Board
Board of Governors of which the above is a copy, on the terms and subject to the conditions of service referred to in that letter and I undertake to commence my duties with the
Regional Hospital Board
Board of Governors on the
 Date..... (Signed)

FORM OF CONTRACT FOR PART-TIME CONSULTANTS OR SENIOR HOSPITAL MEDICAL OFFICERS OR SENIOR HOSPITAL DENTAL OFFICERS

Regional Hospital Board
Board of Governors

Date

Year

Appointment of

I am instructed by the Regional Hospital Board
Board of Governors

to offer you a part-time appointment from the as subject to the terms and conditions of service determined from time to time by the Minister of Health being at present those set out in the document dated June 7, 1949, attached to this letter.

The appointment is subject to the provisions of the National Health Service (Superannuation) Regulations, 1947 and 1948.

The duties attaching to the appointment are as follows:

1. [Regular clinics, etc., setting out hospital(s), days and times of duties.]

2. [Charge of beds at hospital(s) together with any cases in your charge occupying special accommodation under the proviso to Section 5 (1) of the National Health Service Act, 1946.]

3. Occasional duties arising on call at [If possible, specify.]

4. [Adviser to Regional Hospital Board in]

5. [Advisory ("pastoral") visits to the following hospitals:.....]

6. [.....]

7. So far as is consistent with the proper discharge of the above duties, any additional duties undertaken from time to time as substitute for other members of the staff(s) of the above hospital(s) during their temporary absence.

The average number of hours per week which the above duties are estimated to require is and the number of half-days for which payment will be made is accordingly Your [commencing] salary [apart from the value of any distinction award which may be made to you*] will therefore be [rising by annual increments of to Your incremental date will be]

If you agree to accept the appointment on the terms specified above, please sign the form of acceptance at the foot of the enclosed copy of this letter and return to me.

Yours faithfully,

Secretary.

I hereby accept the appointment mentioned in the letter to me dated from the secretary of the
Regional Hospital Board
Board of Governors of which the above is a copy, on the terms and subject to the conditions of service referred to in that letter and I undertake to commence my duties with the
Regional Hospital Board
Board of Governors on the

*To be inserted in consultants' contracts.

Domiciliary Consultants

In addition to the above duties, I undertake/do not undertake, in accordance with the conditions and rates of remuneration set out in paragraph 8 of the above-mentioned terms and conditions of service, to undertake domiciliary consultations during the following times and within the following areas:.....

Date (Signed)

1. The discussions with the medical and dental professions referred to in R.H.B. (49) 40/H.M.C. (49) 30/B.G. (49) 33 have now been completed and the proposals which accompanied this memorandum have been reviewed in the light of the further discussions and of comments received. The document enclosed with this memorandum sets out the terms and conditions of service of hospital medical and dental staff which will replace the interim arrangements now operative and will form the basis of new contracts of service which boards and committees will offer to existing staff, and of all new appointments until further notice. References below such as "Document, paragraph 10 (a)" are references to this enclosed document.

Offer of Contracts to Part-time Staff

2. Boards and committees should already have arranged (in accordance with paragraph 4 of R.H.B. (49) 24/H.M.C. (49) 16/B.G. (49) 18) to extend the provisional contract of all part-time members of the staff until July 4, 1949, and they should now as soon as possible notify each individual concerned of the duties they wish him to perform as from July 5, 1949, if they can by that date adjust details to suit the convenience of both boards (or committees) and practitioner. Where there is no time for this to be done and new contracts cannot be arranged by July 5, boards (or committees) should notify each individual concerned that they propose to extend his interim contract for a further specified period.

3. A part-time contract should not be offered to an officer who holds a whole-time appointment with another board or committee.

Offer of Appointments to Whole-time Staff

4. At the same time boards (and committees) should inform whole-time staff of the duties which they wish them to perform and of the new conditions of service with a view to arranging that the latter operate as from July 5 or as soon thereafter as is practicable. If the officer agrees to the new conditions there will be no further action for the board or committee to take apart from the readjustment of remuneration, etc., from July 5, 1948. A transferred officer who wishes to retain his previous salary scale and conditions of service (including emoluments) on a personal basis as provided for in paragraph 12 (e) of the new terms and conditions of service should be allowed to do so in connexion with any rearrangement of duties which the board (or committee) had included in their offer.

Honorary Appointments

5. An honorary (unpaid) appointment should involve a clear undertaking to render defined services.

Pro Forma Contracts

6. In offering to consultants, Senior Hospital Medical Officers and Senior Hospital Dental Officers new contracts of service on the basis of the enclosed terms and conditions of service, boards may find it useful to consider the suggested forms of contract attached to this memorandum. Variations will, of course, be required to suit individual circumstances. The suggested form has, however, been drawn up with the matters raised in discussion with the professions in mind, and the Minister expects the following points of principle to be observed in drawing up the contracts of consultants, Senior Hospital Medical Officers, and Senior Hospital Dental Officers.

(i) No period of tenure or period of notice should be specified in the contracts.

(ii) All consultants, S.H.M.O.s and S.H.D.O.s are expected, so far as is reasonable and practicable, to deputize for absent colleagues, when necessary in the interests of the Service without the need for the formal appointment of locum.

(iii) (a) There is nothing in the clauses in the pro forma contracts to interfere with the right of a pay-bed patient to make private arrangements under Section 5 (2) with a part-time practitioner, or with the latter's right to recover fees accordingly, or to entitle a patient who has made private arrangements under Section 5 (2) to elect later to pay an inclusive charge under Section 5 (1).

There will be circumstances in which a patient in a Section 5 bed as the private patient of a consultant requires services from another consultant (e.g., a whole-time consultant radiologist or anaesthetist) who is not permitted private practice. It is, therefore, necessary to provide in the contract of such whole-time consultants for treating patients in Section 5 beds who have not made private arrangements for that treatment under Section 5 (2), and in respect of duties at any hospital where the patients in Section 5 beds may need their care the acceptance of such a clause should be made a condition of a contract. The acceptance of such a clause will also enable a patient who has been referred to the whole-time consultant by his family doctor to arrange to be treated in a Section 5 pay-bed.

(b) In the case of both whole-time and part-time officers, the general duties undertaken by them include the duty of treating without any additional remuneration and without any right to recover private fees, patients in their charge who are occupying Section 5 accommodation under the proviso to Section 5 (1) of the Act.

(iv) Where the duties of whole-time officers necessitate their residence at, or within reasonable distance of, the hospital, an appropriate clause (as suggested in the pro forma contract) should be included in the contract.

(v) In offering contracts which include a clause relating to domiciliary consultations boards should aim at reconciling the needs of the domiciliary specialist service in the particular area with the wishes of the whole-time and part-time officers concerned, but they may find it necessary in certain areas to insist on the inclusion of an appropriate clause in the contract of service of a whole-time officer if that is the only way in which the service in that specialty can be provided.

7. Further points which bear on the suggested forms of contract are dealt with among the following notes, which are intended to guide boards and committees on the application and interpretation of the terms and conditions of service.

Senior Hospital Medical and Dental Officers (Document, paragraph 2 (a) and (b))

8. The term "Senior Hospital Medical (or Dental) Officer" is merely used for convenience in defining the grade, and will continue to be so used in official documents. It need not be adopted as a title describing individual officers holding the posts in this grade, and boards are free to use whatever terminology may be preferred—e.g., an anaesthetist holding a post in the senior hospital medical officer grade might be given the title of "Anaesthetist," a consultant in the same field being called a "Consultant Anaesthetist."

9. It is intended that Senior Hospital Medical and Dental Officers in non-teaching hospitals should be appointed and paid by Regional Hospital Boards, and a further note will be circulated about this.

Medical Superintendents (Document, paragraph 2 (c))

10. The objective of boards should be to reduce to a minimum the time given by medical staff to administrative duties, and to enable them to devote their energies to clinical work in their appropriate grade.

11. In computing salary rates boards may ignore any administrative duties of which they find it impracticable to relieve a medical superintendent where these duties occupy only a small proportion of the officer's time. The Minister will be prepared to advise boards or committees on any point of difficulty.

12. The appropriate rate for hospital administrative staff will be

(a) where the hospital is the only one administered by the hospital management committee, the salary scale for the secretary of the hospital management committee, and

(b) where the hospital is one of a group of two or more administered by the hospital management committee, the appropriate to an assistant secretary in charge of the hospital.

Registrars (Document, paragraph 3)

(a) Terminology

13. At present the different titles used in different hospitals to describe holders of "trainee specialist" posts give rise to confusion; in future, to avoid misunderstanding, the term "Senior Registrar," "Registrar," and "Junior Registrar" should be universally adopted for all purposes, including advertisements, in describing these posts as defined in the enclosed document and officers holding them. At the same time the title of other grades of officers at present using the term "Registrar" should be changed.

(b) Grading of Registrars

14. If they have not already done so, Regional Hospital Boards should ask their professional Review Committees to determine, after consultation with the medical committee of the hospitals concerned and the appropriate postgraduate deans or deans, the grade of post (i.e., Senior Registrar, Registrar, Junior Registrar) held from time to time since July 5, 1948, by "trainee specialists" (including holders of "supernumerary Class III posts under the scheme for postgraduate education of demobilized medical officers) in hospitals in their region. The Review Committee should make their recommendations to the Regional Board, who will then inform the Hospital Management Committees concerned.

15. In the case of teaching hospitals, the Board of Governors should ask the medical advisory committee, in consultation with the appropriate dean or deans, to make similar recommendations with regard to the corresponding posts and practitioners in the teaching hospital group.

(c) Retrospective Adjustment of Salaries (see paragraph 91 (b) below)

(d) Transitional Arrangements as regards "Supernumerary Registrar Posts"

16. Holders of Registrar posts supernumerary to establishments are expected, as soon as possible, to seek posts within a hospital's normal establishment if they need further hospital post in order to gain experience. To minimize hardship during the transitional period, however, Boards of Governors and Hospital Management Committees may retain men of accepted ability holding Class III posts under the scheme for postgraduate education of ex-Service officers for a further period of 12 months in "supernumerary" posts after the termination of their current appointment in cases where the latter is due to end on or before Sept. 30, 1949.

(e) Movement of Registrars between Specialties

17. A Registrar in general medicine or general surgery will, in some cases, after gaining the appropriate experience, wish to specialize in some other branch of medicine or surgery—e.g., radiology, paediatrics, pathology, ophthalmology, thoracic surgery. In such cases the post to which he is appointed in the new specialty will usually be the grade below that attained in general medicine or general surgery; where a Senior Registrar takes a Registrar post in this way he will, in accordance with the terms and conditions of service, be paid at the higher rate (i.e., £890 per annum) for a Registrar post as long as he holds a post of that grading; if subsequently he obtains a Senior Registrarship in the new specialty, he will commence at the salary for the first year of a Senior Registrar post (£1,000 per annum).

House Officers (Document, paragraph 4 (a))

18. Whatever period of tenure may have been customary in the past for House Officer posts, they should in future invariably be tenable for periods of six months. This should not prevent movement from one department of a hospital to another during the six months' period.

Junior Hospital Medical Officers (Document, paragraph 4 (b))

19. These are whole-time appointments only.

Part-time Appointments (Document, paragraph 5)**Consultants (Document, paragraph 5 (a))**

20. The following is an example of the application of paragraph 5 (a) of the document :

A physician divides his time as follows :

Work	Estimate of Time Required by an Average Practitioner	Total Weekly Time (in Hours)
2 out-patient clinics ..	2 hrs. weekly + 1 hour's travelling in 11 " " each case	4½
"Pastoral visits" to outlying hospitals ..	One day of seven hours fortnightly, including travelling	3½
Irregular hospital visits	2 hours weekly, including travelling	2
Charge of beds ..	9 hours weekly—½ hour's travelling daily for 6 days	12
Adviser to board ..	8 hours monthly	2
	Total	24
		= 7 "half-days"

For this the physician would receive eight-elevenths of the appropriate whole-time remuneration—i.e.,

$$\frac{7}{11} + \frac{(11-7)}{44} = \frac{8}{11}$$

21. It will be noted that determination of the number of "notional half-days" does not involve calculation of the actual number of hours worked on any particular day or in any particular week by any particular consultant. The board are expected to make a pre-contract assessment of the duties attached to the post in terms of the time which should be taken by an average practitioner to perform those duties. It follows from this that there is no need for consultants to "clock in and out" so as to record the hours at which they arrive and depart, and that differences in the length of time taken by different consultants for exactly similar duties will not be reflected in their rates of remuneration. Where consultants are engaged in teaching duties concomitantly with their clinical work the pre-contract assessment of the time required by an average practitioner to perform the duties of the post will reflect the fact that the time required for a teaching ward round or out-patients' clinic, etc., would normally be greater than that required by an average practitioner engaged on clinical work alone—i.e., the board should *not* reduce the average time required for the work to correspond with the average time which would be required to do the ward round, etc., in a hospital where teaching is not carried on. The only factor in determining the "notional half-days" which will be directly related to the circumstances of the individual consultant is travelling time, which will depend in each case on the distance between the consultant's home or consulting-room and places of duty, and any other relative considerations. Time required for examinations and reports which fall within Category I in the Schedule to paragraph 14 of the document should also be taken into account in assessing the number of "notional half-days"; but time required for work which falls within Category II of that Schedule should, like all private patient work, be excluded.

22. It is clear that the time required for the performance of the duties of the post is not capable of meticulously exact assessment. The board should agree with the consultant concerned the number of "notional" half-days which as nearly as can be foreseen adequately expresses on the basis explained above the extent of the duties required of him, bearing in mind that the table relating the "number of hours weekly" to the "number of notional half-days" gives the consultant the benefit of marginal overlaps—i.e., there is no provision for payment for fractional half-days.

23. This pre-contract assessment of time should be subject to reconsideration at any time (at the instance of either board or practitioner); but if re-examination is called for in the light of experience it should still be remembered that the assessment is based on the time which would be reasonably required by an average practitioner and not necessarily on the time which is actually being taken by the individual.

24. The pre-contract assessment of travelling time will not be capable of precise computation; but it is really the same as that for which travelling expenses are payable, and occasional

comparison of time reckoned under paragraph 5 (a) of the document with the mileage allowed for expenses under paragraph 19 of the document would be sufficient to ensure a reasonable degree of accuracy.

Part-time Registrars (Document, paragraph 5 (c))

25. As a general rule all Senior Registrars, Registrars, and Junior Registrars will hold whole-time posts for a definite period. Occasionally a whole-time appointment might be divided between two or more hospitals; a true part-time registrar post might be suitable in the following cases:

(a) an officer who has obtained a part-time consultant appointment on the staff of a non-teaching hospital might retain a part-time appointment as senior registrar on the staff of a teaching hospital; and

(b) a practitioner in general practice whose object is ultimately to apply for a consultant appointment might, if he could not afford to give up his practice to take a whole-time appointment, hold a part-time post in a registrar grade, in order to gain the experience to equip himself to make such an application.

26. Posts in the registrar grades should normally, however, be reserved to practitioners who are training in a particular specialty with a view to attainment of consultant status. A general practitioner without such a specific ambition may be adequately catered for with a part-time "clinical assistantship" (see paragraph 43 (a) below).

Higher Rates of Part-time Remuneration (Document, paragraph 5 (e))

27. The Minister would be prepared to approve higher rates of remuneration only in cases where some special inducement was necessary to fill an essential appointment and where the difficulty could not be avoided in any other way—e.g., by combining the part-time appointment with appointments in other hospitals. This situation might arise in the case of an essential consultant appointment at a hospital in a small country town not warranting whole-time employment, where the duties could not be combined with similar duties in nearby hospitals, and where it would be difficult for the consultant to supplement his hospital appointment by private practice; but the circumstances of each case will be considered on their merits.

Exceptional Consultations (Document, paragraph 6)

28. It should very rarely be necessary for payments to be made to consultants for services of the kind referred to in this paragraph. The "exceptional consultation" is intended to be really exceptional. In particular, such payments should never be necessary in the case of consultants who are in contract with the board on whose behalf the exceptional consultation is undertaken; and in the case of consultants who are not in contract with the board the special payments should be necessary only where the consultations concerned are not the realization of an anticipated liability. The following notes explain more fully what is meant by this:

(a) Where the consultant is under contract with the board primarily on account of regular duties at a particular hospital or hospitals, his liability to be called occasionally to other hospitals should be allowed for in fixing the contract (on the lines of the entry "Irregular hospital visits" in the example given in paragraph 20 above), even though it is impossible to forecast the exact number of times his services will be called for. What is required is a rough assessment of his liability to be called upon.

(b) If a consultant's services for a board do not include regular duties at any hospital but he is called upon when required, his liability should be assessed in exactly the same way and expressed in terms of notional half-days per week to form the basis of a contract of service. (Alternatively, in appropriate circumstances an honorary appointment in respect of such occasional consultations might be acceptable to the consultant.)

(c) The same principle applies when a consultant has a contract for regular services with one board and is called in to the hospitals of another board when required. Any services of this kind known to be required from the consultant by the latter board should be dealt with as in (b) above.

(d) Where part-time appointments are offered which include (or even cover nothing more than) a liability to be called on for irregular visits, the appointments are subject to the normal maximum remuneration (9½ elevenths of the appropriate whole-time salary): and where the consultant holds appointments with more

57. For the purposes of the principle indicated at (a) under "Category I," the phrase "reference from a medical source" means reference from a medical or dental practitioner or practitioners (e.g., a medical board) who, having clinically examined a person, for any reason require a second opinion. It does not mean reference from a medical administrative officer who has not clinically examined the person referred.

58. The inclusion in "Category II" of general practitioner services given by a hospital medical officer under Part IV of the Act to members of the hospital staff who are on his "list" means that either a whole-time or part-time officer may undertake this work and retain the Executive Council fees payable. This is however subject to the general overriding condition that officers should not be allowed to undertake "Category II" work unless the amount of work involved is consistent with the proper discharge of their hospital duties. Where it is convenient for such services under Part IV of the Act to be performed by whole-time staff, it may therefore be necessary, in a large hospital, for several whole-time officers to divide the work between them, each applying to the Medical Practices Committee (through the Executive Council) for inclusion in the medical list and if his application is granted seeking the consent of the Executive Council to a limitation of his "list."

Retired Consultants (Document, paragraph 15)

59. There is nothing to prevent the offer to a consultant of 70 or over of an honorary appointment in respect of exceptional calls on his services, as indicated in paragraphs 6 and 15 of the terms and conditions of service.

60. In the past, the retiring age has varied from hospital to hospital and there will be consultants who, during the last few months, have retired at ages below 65 to the honorary consultant list. Officers who retired at an earlier age after July 5, 1948, should be offered re-employment in an active capacity until they reach retiring age.

61. Boards may also find it useful to offer re-employment in an active salaried capacity to officers who retired at ages below 65 before July 5, 1948, until such time as they reach retiring age, although they would have no obligation to do so; if there are such officers whom the boards cannot employ in an active capacity, they should be prepared to give honorary unpaid appointments as described in paragraph 6 to any who desire them.

62. In no case could any guarantee be given to reinstate the officer in his former post, because it may have been filled in the meantime.

63. Officers re-employed in these circumstances would not, of course, receive pay in respect of the period between retirement and reappointment, but upon reappointment in an active capacity the rate of pay should be as if there had been no break in service.

64. Where a retired consultant holds an honorary appointment, it enables him to treat private patients in Section 5 beds and he is not precluded from claiming travelling and subsistence expenses in the usual way in respect of the duties of his appointment.

65. If a retired consultant agrees to undertake to give domiciliary consultations under the board's scheme, the appropriate domiciliary consultation fees will be payable.

Tenure of Post (Document, paragraph 16)

66. No period of tenure should be specified in the contract of service of any officer except Registrars, House Officers, and certain types of "clinical assistantships," etc., arising under paragraph 43 of this memorandum. In the absence of any stipulation in the contract regarding notice of termination of appointment by either party, the board will be entitled to expect reasonable notice to be given to them by any officer who wishes to resign his appointment. The National Health Service (Appointment of Specialists) Regulations, 1948 (S.I. 1948, No. 1416) will be amended to remove the requirement that the duration of the appointment shall be stated in the advertisement.

67. Where whole-time or part-time consultants are displaced from their appointments as a result of, e.g., a change of use of particular premises or a review of hospital establishments, or where for similar reasons a part-time consultant's duties are seriously disturbed, the board should so far as practicable give the consultant or consultants concerned the opportunity of undertaking similar duties elsewhere. As was explained in a similar connexion in R.H.B. (49) 70/B.G. (49) 58, it will be more difficult for a Board of Governors than for a Regional Hospital Board to do this, as their administrative control extends over a much narrower field, but they should seek the co-operation of neighbouring Regional Hospital Boards in endeavouring to arrange for the offer of similar work.

Leave (Document, paragraph 18)

Annual Leave (Document, paragraph 18 (a))

68. An officer may be allowed to take, at any time up to Dec. 31, 1949, any balance of annual leave which may be due to him on the basis of the new terms and conditions of service in respect of the period to March 31, 1949.

69. Where an officer moves from one employing authority to another within the National Health Service, his service should be regarded as continuous for purposes of entitlement to annual leave, including the six months' qualifying period. The leave due under the second employing authority in the year in which the change takes place will therefore be the amount of leave due for the full year less any leave taken under the first authority.

70. In a year of transition from a salary of less than £1,000 to one of £1,000 or more, the leave entitlement for the year should be determined on a proportionate basis.

71. Saturday should be regarded as a full working day for purposes of annual leave.

72. Officers must notify the board or hospital management committee when they wish to take annual leave, and the granting of such leave will be subject to approved arrangements having been made for their work to be done during their absence.

"Study" Leave, Conferences, etc. (Document, paragraph 18 (d))

73. It will be appreciated that where, on the instructions of the board, officers undertake teaching or examining duties; attend meetings or conferences, or visit clinics, etc., no question of special leave arises and the officers should be regarded for all purposes, including the payment of expenses, as being on the service of the board.

74. When considering applications under the last sentence of paragraph 18 (d) (i) of the document for permission to undertake remunerative work during a period of leave with pay, boards or committees should give permission as regards fees for examining in medical or dental subjects.

75. A period of absence on study leave without pay may be allowed to count for purposes of increment at the discretion of the leave-granting authority. In general, an absence of this kind should be reckoned as incremental service where the purpose for which the leave is taken is directly connected with the officer's work and may be expected to increase his usefulness as a member of the staff of the National Health Service.

76. In cases where study leave has been granted with pay, travelling expenses and/or subsistence allowances may also be granted where in the opinion of the board it will be to the advantage of the Service to do so. Expenses may be granted wholly or in part. Regional Hospital Boards and Boards of Governors may combine to defray the whole or part of these expenses in an individual case.

77. While it is desired to give boards the maximum of discretion in the granting of study leave, it is necessary to secure a substantial measure of uniformity in the matter of defraying expenses. Boards will therefore be required, within their approved budgets, to limit their annual expenditure on all expenses granted in connexion with study leave (including for this purpose the expenses of officers who are teaching, attending meetings, etc., at the instruction of the board—see paragraph 73 above) to certain prescribed maxima. In the case

of Regional Hospital Boards (and covering also Hospital Management Committees in the region) these are as follows:

£1,200 Oxford, Cambridge.

£1,600 Newcastle, Leeds, Sheffield, Liverpool, Bristol, Wales

£2,000 Metropolitan regions, Manchester, Birmingham.

Each board of governors will be notified individually before July 5, 1949, of the maximum to which they will be required to adhere. The maximum will vary according to the size and circumstances of the hospital, but will in no case exceed £1,200, and in the case of undergraduate teaching hospitals will in no case be less than £800.

78. Where the expenditure of a board on expenses for the year 1949-50 is likely to exceed the maximum referred to above, and it is not possible to meet the additional cost from "free money" at the board's disposal, application should be made by the board for authority to increase the amount allocated within the budget for this purpose.

79. It is hoped at an early date, in the light of experience already gained in the Ministry, to give further guidance on the granting of study leave.

80. The study leave arrangements provided for in the terms and conditions of service and in this memorandum are provisional and will be subject to reconsideration when experience has been gained of their operation.

Sick Leave (Document, paragraph 18 (e))

81. The holding of an honorary (unpaid) appointment—e.g., by a specialist at a voluntary hospital prior to the appointed day—should be regarded as constituting service under an employing authority for the purposes of subparagraph (2) (b).

Special Extended Leave: Teaching Posts in Colonial Universities

82. It will be open to a regional hospital board or board of governors to allow consultants in their employment extended leave of absence without pay to enable them to take up teaching posts in Colonial universities, provided they undertake to return to the hospital service immediately on the termination of their Colonial employment. The period of leave granted for this purpose should in no case exceed three years. At the end of such leave the board should offer the consultant a new post not necessarily the one he held before his absence) or help him to find a post with another board; and the period of leave without pay should count for increment. The Minister will advise on the preservation of superannuation rights in such circumstances.

83. The Minister is at present considering allowing facilities for special leave without pay for other similar purposes, and boards will be advised in due course.

Expenses (Document, paragraph 19)

Subsistence Allowances (Document, paragraph 19 (f))

84. For the time being, any case in which the officer's absence exceeds, or is likely to exceed, 28 nights should be reported to the Ministry for determination of the reduced rate payable.

Expenses of Candidates for Appointment (Document, paragraph 19 (i))

85. Payment of the expenses of candidates other than those referred to in paragraph 19 (i) of the document should be governed by the normal rule—i.e., no subsistence should be paid, but the full cost of third-class railway fare or bus fare from their ordinary place of residence (in the case of candidates travelling from abroad, from the port of landing in this country) or the interview may be refunded if the expenditure, calculated on this basis, exceeds 5s.

Payment of Mileage Allowance to Whole-time Officers for Journeys from Home to Main Hospital (Document, paragraph 19 (d))

86. Mileage allowance for journeys between home and hospital will be payable where an official journey of the kind described in this paragraph is undertaken and also where a whole-time officer has a defined liability to undertake such journeys though in fact he may not receive a call to do so. In the case of a

whole-time officer liabilities of this sort should always be closely circumscribed and defined and there should be no question of an indefinite requirement to have the car available at the hospital on days other than those to which the liability is specifically related.

Secretarial Assistance

87. Questions have arisen from time to time about the payment of expenses to consultants in respect of secretarial services which they have provided for themselves at hospitals. A board of governors or hospital management committee may provide secretarial services at a hospital, on either a whole-time or part-time basis, for the benefit of medical staff, but neither a board nor a management committee has power to reimburse a practitioner for any part of the cost he incurs in engaging his own employee. It is for the board of governors or hospital management committee to decide how far they consider it necessary to provide such services.

Medical Examination on Appointment (Document, paragraph 20)

88. The Minister is discussing further with representatives of the profession the future application of the provisions of this paragraph to house officers, and further guidance will be given as soon as possible.

Retrospective Application

89. The intention is that so far as possible the whole of these terms of service should be applied with effect from July 5, 1948. Remuneration and detailed conditions of service are interdependent, and the application retrospectively of the former should ideally be accompanied by the application retrospectively of the latter.

90. It is clear that this ideal will not always be capable of realization. It is not always possible to give retrospective effect to new privileges or to withdraw retrospectively privileges already enjoyed. Boards are therefore allowed discretion in making adjustments of salary, item of service payments, expenses, etc., relating to the period July 5, 1948, to July 5, 1949, on the understanding that so far as practicable the general effect should be that which would have been achieved had these terms and conditions of service taken as a whole been in operation since the appointed day.

91. The following notes, which are not intended to be exhaustive, give guidance to boards and committees on the way in which their discretion might be exercised on certain questions which appear to the Minister likely to arise, and which are not dealt with elsewhere in this memorandum.

(i) General

Officers will be paid from July 5, 1948, in accordance with their recent grading by boards (except where different posts have been held by the same officer during the period). Where the salary already paid between July, 1948, and July, 1949, exceeds the salary (including any distinction award) to which the officer becomes entitled retrospectively, boards should not attempt to recover the excess. Where, however, whole-time officers have been entitled under their old conditions of service to retain or have remitted to them private fees, the amount of such fees earned by them during the period to which the retrospective application relates should be offset against any upward adjustment of remuneration.

Retrospective payments of salary will have to be made to officers who have retired, or to the estate of officers who have died, since July 5, 1948.

(ii) Distinction Awards (Document, paragraph 1 (b))

Retrospective payments will have to be recalculated for consultants who subsequently receive the initial distinction awards. Retrospective payment should not be withheld in the expectation of an early award except at the consultant's request.

(iii) Clinical Teachers holding a Distinction Award (Document, paragraphs 1 (b) and 9)

If the clinical teacher concerned holds an appointment of the kind described in paragraph 9 (1) of the document the amount of the award payable in his case (from July 5, 1948, or such later date as he first held the appointment) will be remitted by the Regional Hospital Board/Board of Governors concerned to the University or Medical or Dental School, who will include it as an element of his remuneration.

If he holds an appointment of the kind described in paragraph 9 (2) of the document he receives the appropriate value of the award from the Regional Hospital Board/Board of Governors.

(iv) *Medical Superintendents (Document, paragraph 2 (c))*

The new salary (composed of salary for clinical work and salary for administrative work) should be paid retrospectively according to the officer's grading in the clinical and administrative fields respectively since July 5, 1948 (except for transferred officers opting to keep their old salary and conditions of service).

(v) *Senior Registrars, Junior Registrars, and House Officers (Document, paragraphs 3 and 4 (a))*

The posts which an officer has held from time to time since July 5, 1948, should be reviewed and classified in accordance with the new grading. Remuneration should then be adjusted retrospectively, but where the salary paid during the interim period or any part of it exceeds the salary appropriate to the post as now graded, the overpayment need not be recovered. This applies to holders of "supernumerary posts" under the scheme for post-graduate education of ex-Service officers just as to holders of posts within hospitals' present establishments. Where holders of Class III posts under the postgraduate scheme for ex-Service officers have held posts which are now graded as House Officer posts, the Class III remuneration which they have received should therefore be allowed to stand.

In a small number of cases retrospective upward adjustment of salary will have to be regulated so as to avoid retrospective overpayment of Further Education and Training grants awarded by the Ministry of Education. The hospitals concerned will be notified individually at the earliest practicable moment of the action they should take in this matter.)

In applying retrospectively the new rates for House Officers the period since the date of registration during which posts in this grade have been held should be divided into six-monthly periods (irrespective of the period of tenure which in practice attached to the posts), the remuneration for the first six months after registration being calculated at the rate of £350 per annum, for the second six months at the rate of £400 per annum, and thereafter at the rate of £450 per annum.

(vi) *Blood Transfusion Staff Employed on a Sessional Basis*

For these staffs, the pre-appointed-day arrangements have continued in operation throughout the interim period. If boards have sufficient information to reassess their sessional work during the period in terms of a part-time contract the new salary rates may be applied on that basis. (Where the number of "notional" hours weekly is two or less, the provisions in paragraph 10 (b) of the document may be applied.)

(vii) *Payment for Exceptional Consultations (Document, paragraph 6)*

Exceptional visits to hospitals within the area of the employing board were not intended, in the interim period, to attract extra payment where the consultant was already earning the maximum of £1,600. If such visits have in fact been remunerated, then if the consultant was employed for nine or more half-days per week the payment made in respect of exceptional visits should be offset against the additional salary payment now due to adjust the interim salary to the higher rates.

Exceptional consultations which would attract payment under paragraph 6 of the document should be remunerated retrospectively at the new rate.

Where a consultant was being paid provisionally less than the maximum provisional rate of £1,600 per annum, or was being paid £1,600 but working less than nine half-days per week, and has been paid in addition for exceptional visits to hospitals within the area of the employing board; then, if the application of paragraph 5 (a) of the document would have enabled his liability to undertake those visits to be taken into account in the assessment of the number of notional half-days per week on which his salary was reckoned, and an adjustment of the number of half-days retrospectively on this basis is possible, the consultant should be paid retrospectively for the adjusted number of half-days, and the item of service payments which have been made for the exceptional visits offset against the upward adjustment of remuneration.

There was no provision in the interim arrangements for exceptional visit fees for general practitioners. Any *ad hoc* payments which have been made may be adjusted retrospectively where practicable to conform with the rate of payment now laid down.

Similar questions to the above may arise on the payment of locum fees during the interim period: if so, they should be dealt with in the same way.

(viii) *Domiciliary Consultations (Document, paragraph 8)*

Where whole-time officers have been paid for domiciliary visits, the payments need not be offset against any upward adjustment of salary.

Where, however, the interim rates of payment were more favourable to a consultant (whole-time or part-time) than the new rates (e.g., the 10 guineas payment for major operations), the overpayment should be offset against upward adjustment of other domiciliary service payments or of salary.

Where records have been kept of domiciliary consultations undertaken in excess of the maximum for which fees were payable during the interim period, payment for the consultations so recorded may now be made at the new rates, subject to the revised maximum.

(ix) *Retention of Fees (Document, paragraph 14)*

The Minister realizes that it will be impracticable to apply retrospectively the provisions of paragraph 14 of the document unless in particular circumstances records have been kept pending settlement in the light of these terms and conditions of service.

(x) *Residential Appointments (Document, paragraph 17)*

The basis of charge in place of a valued emolument should be retrospective to July 5, 1948.

(xi) *Study Leave (Document, paragraph 18 (d))*

Any expenses granted in connexion with study leave taken after July 5, 1949, which was authorized by the Minister before that date will count against the maximum referred to in paragraph 77 above.

(xii) *Sick Leave (Document, paragraph 18 (c))*

Where the new provisions are more generous than the old, the balance of pay may be paid in respect of sick leave taken during the interim period. Where under the old conditions payments have been made on a more generous basis there should be no recovery (or offset against retrospective adjustment of salary rates).

Retrospective payments should take into account deduction of National Insurance benefits payable.

(xiii) *Expenses (Document, paragraph 19)*

The higher rates of travelling allowances and expenses (and the conditions attaching to them) may be applied retrospectively so far as possible. Where detailed adjustment is impossible, settlement may be made by agreement between the board (or hospital management committee) and the officer concerned.

Recovery need not be made from officers who have received subsistence allowances during the interim period at higher rates than those to which they are now entitled.

(xiv) *Medical Examination on Appointment (Document, paragraph 20)*

These provisions should not be applied retrospectively: i.e., it is not intended that officers who obtained hospital appointments between July 5, 1948, and the date of receipt of this memorandum should now be required to undergo a medical examination.

THE RIGHT TO ARBITRATION

At a meeting of the General Medical Services Committee on June 2 the chairman, Dr. S. Wand, reported on a discussion which he and the Secretary had had at the Ministry of Health, the Minister himself being present, on the question of the remuneration of general practitioners in the Service. He said that the Minister had insisted that it was necessary, before he could make any decision, that he should know exactly what each doctor was receiving for each item of service in addition to the capitation fee. It appeared that the results of the inquiry which the Ministry was making into the actual earnings of general practitioners could not be completed and collated until the middle of July. The Minister had been informed that in the event of an unsatisfactory outcome the profession would desire recourse to arbitration, but the Minister had stated that such recourse must be subject to his consent in any given case.

Attention was called to Clause 12 of the amending Bill, which laid it down that there could be a determination of issues by arbitration only when the Minister agreed that the matter in question should be so referred. This meant that it would never be possible for the profession, having disagreed with the Minister on any major financial issue, to insist on arbitration, since the Minister's approval was always necessary.

Dr. Dain (Chairman of Council) said that until the amending Bill appeared it was assumed that they were entitled to take the Minister to arbitration on remuneration whenever they liked to do so. He felt that the profession must never allow itself to be in a position in which the Minister could refuse its

demand for arbitration. Higher Civil Servants were excluded because of their close contact with the State, but the profession was not in that position. The profession must stand on its right to demand arbitration on the remuneration question whenever it arose, and the Minister could do the same. He hoped that the Government would appreciate that this was a fundamental question to the profession and would be prepared to accept such an amendment.

The committee unanimously resolved that on the remuneration issue, should no agreement be reached, the right to have the matter determined by arbitration should be demanded, and that in the meantime in the various areas the profession should be informed of the position.

It was agreed to call an additional meeting of the committee on July 28, but should any fresh major development arise the committee would be recalled at once.

Other matters which came before the committee will be reported in a subsequent issue of the *Supplement*.

BRITISH MEDICAL ASSOCIATION

ANNUAL REPRESENTATIVE MEETING

MOTIONS AND AMENDMENTS FROM DIVISIONS AND BRANCHES

War Memorial

Amendment by HARROW: That this meeting totally opposes the action taken by the Council with regard to the choice of a fountain as a war memorial, as described in para. 6 of the Annual Report of Council; it requests that no further action should be taken by Council and suggests that the sum of £10,000 should be devoted to educational scholarships for the dependants of the fallen. (Similar motions by other Divisions.)

NATIONAL HEALTH SERVICE

Arbitration

Motion by READING: That this meeting advises the profession to resign from the National Health Service unless the Minister guarantees that in the event of disagreement between representatives of the profession and himself all matters shall be submitted to arbitration and that, in the event of disagreement on the betterment factor, this be submitted immediately to arbitration.

Motion by RICHMOND: That the right of arbitration must be an integral part of the Whitley Council machinery set up for the medical profession, and must be incorporated in the Amending Act.

Motion by KINGSTON-ON-THAMES: That as the Minister of Health has withdrawn the official assurances and undertakings, repeatedly given to the profession, on the question of arbitration in the event of a dispute, this Representative Body demands that effective action be taken forthwith to insist that arbitration machinery be set up, and that demands for arbitration by the profession shall not be subject to the Minister's veto.

Motion by KENSINGTON AND HAMMERSMITH: That this meeting regrets the delay in establishing the Whitley machinery on the question of doctors' remuneration, and expresses its strong conviction that Whitley machinery without the possibility of arbitration will be of little avail.

Motion by MID-ESSEX DIVISION: That the Minister's refusal to grant the right of appeal in disciplinary cases, or arbitration if the Whitley machinery breaks down, shows an autocratic attitude which the medical profession will not tolerate.

Overseas Visitors

Motion by GATESHEAD: That this meeting expresses strong disapproval of the position whereby any alien has free access to all medical services paid for by the British taxpayer, while such taxpayer is denied free medicine if he elects to make a private contract with his general practitioner.

The First Year of the Service

Motion by MARYLEBONE: That this meeting of representatives from all parts of the country regretfully records the fact that, during the first year of the National Health Service, the

Minister and the Ministry of Health have shown little or no desire for co-operation with the medical profession in its efforts to serve the public; that they have met the profession's suggestions with indifference and procrastinations; that they have been guilty of breach of faith; and that, particularly for these reasons, the Service is falling far below the standard the public were led to expect.

GENERAL MEDICAL SERVICES

Remuneration of General Practitioners

Motion by BUCKINGHAMSHIRE: That, unless negotiations result in a financial settlement satisfactory to the profession as a whole before Sept. 30, 1949, this meeting instructs the Council to advise mass resignation of the profession from the N.H.S.

Motion by BELFAST: That, owing to the unsatisfactory situation which has arisen, due to the indefinite postponement of discussion by the Ministry of Health of the reasonable and documented case put forward by the General Medical Services Committee for increasing the Central Pool by £16½ million, this meeting demands that further delay shall not be tolerated, and that the Association take immediate steps to organize a mass withdrawal from the Service.

Motion by KINGSTON-ON-THAMES: That, the present capitation rate never having been agreed to by the profession, the Representative Body demands that the contemplated improvements in remuneration shall have effect retrospective to the commencement of operation of the National Health Service Act.

Motion by BLACKPOOL AND FYLDE: That this meeting gives full support to the Conference of Local Medical Committees in seeking an adjustment of general practitioner remuneration on the basis of the report prepared by the General Medical Services Committee, and stresses the urgency of the matter in view of financial hardship which exists, particularly in certain parts of the area.

Motion by GREENWICH AND DEPTFORD: Para. 26. That this meeting deplores the Minister's attitude regarding the reconsideration of remuneration.

Vaccination and Immunization

Amendment by DERBY: That the fee for vaccination should be one guinea and that the fee for immunization should be 5s. for each injection.

Motion by GREENWICH AND DEPTFORD: That this meeting considers that the Minister's continued refusal to agree to the payments of fees for immunization and vaccination is indefensible.

Motion by GATESHEAD: That, until it be established that local authorities are responsible for the payment to practitioners of fees for the performance of vaccinations and immunizations, it is recommended that no reports of the performance of such services be rendered.

Provision of Medicines and Appliances for Private Patients

Motion by CHELSEA AND FULHAM: That the facilities of the pharmaceutical services should be free to private patients.

Medical Treatment of Overseas Visitors

Motion by KENSINGTON AND HAMMERSMITH: That extra money be put into the Central Pool in respect of foreign visitors who become entitled to treatment under the National Health Service.

Dental Haemorrhages

Amendment by CITY OF EDINBURGH: That treatment should not be refused in cases of dental haemorrhage, but that pressure should be continued to obtain a fee for such emergency service.

Motion by GATESHEAD: That in the event of his being called upon to deal with a dental haemorrhage a medical practitioner should be able, as a dentist is able, to claim suitable payment from the Dental Estimates Board.

Frivolous or Unjustified Emergency Calls

Motion by LINCOLN: That the B.M.A. take all steps to persuade the Minister of Health to set up a series of rules for patients comparable to those used under the National Health Insurance Act.

General

Motion by MID-ESSEX: That this meeting presses for a speedy settlement of a number of problems which have now been outstanding for nearly a year—namely, (1) The provision of health centres, (2) Payment for mileage in maternity cases, (3) Payment for urban mileage, (4) Payment for mileage in connexion with the examination and certification of persons of unsound mind, (5) Payment for vaccination and immunization, (6) Increase in payment for temporary residents.

Motion by TORQUAY: That this meeting congratulates Council on the vast volume of work contained in its Annual Report, but regrets that so little improvement in the terms of service under the National Health Service Act has accrued from it.

Superannuation

Motion by WEST DENBIGH AND FLINT: That superannuation should not be deducted on the cost of expensive drugs supplied by rural practitioners.

Motion by BLACKPOOL AND FYLDE: That this meeting requests the General Medical Services Committee to examine the whole question of superannuation, with particular reference to the lack of "cover" provided during the first 10 years of service.

Range of Service

Motion by GATESHEAD: That the Ministry of Health be requested to correct forthwith their misinterpretation of Regulation 6 (1) of Schedule 1 of the General Medical and Pharmaceutical Services Regulations.

References to Regional Medical Officers

Motion by GATESHEAD: That the attention of the Ministry concerned be drawn to the waste of doctors' time caused by the recent great number of unnecessary references to Regional Medical Officers.

Notice to Patients by Executive Councils

Motion by MARYLEBONE: That the attention of the Minister should be called to the fact that executive councils are giving insufficient notice to the patients of doctors resigning from medical lists.

Allocation of Patients

Motion by EAST KENT: That no patient shall be allocated to a practitioner from whose list he or she has previously been removed at the request of the practitioner concerned.

Doctors' Calls

Motion by WEST DENBIGH AND FLINT: That all messages should be sent to a doctor's house before 10 a.m., with the exception of emergencies, and that this instruction should be printed on the N.H.S. medical cards, as was done prior to July 5, 1948.

Form O.S.C.1

Motion by EAST KENT: That Form O.S.C.1 is redundant and should be abolished.

Purchase Tax

Motion by CHELSEA AND FULHAM: That there should be no purchase tax on drugs.

Travelling Expenses

Motion by LINCOLN: That doctors when travelling at the expense of the Ministry of Health should be allowed first-class fares.

Domiciliary Physiotherapy

Motion by TORQUAY: That as a matter of principle it should be within the power of the general practitioner to order domiciliary physiotherapy for patients when in the practitioner's opinion it is necessary.

CONSULTANTS AND SPECIALISTS

Motion by EAST KENT: That the democratically elected Consultants and Specialists Committee is the body which should represent its constituents, and there should be no representation of the Colleges as such on the Negotiating Committee.

Motion by EAST KENT: That it is essential that on all specialists committees non-teaching consultants and specialists should be represented equally with members of teaching hospital staffs, having regard to the large part they play in the Hospital Service.

Proposed Terms and Conditions of Service of Hospital Medical Staff

Motion by KINGSTON-ON-THAMES: That this Representative Body deplores the delay in offering final terms of service to consultants and specialists and demands that such terms be offered forthwith for their consideration.

Security of Tenure

Motion by KINGSTON-ON-THAMES: That the Representative Body protests most emphatically at the procedure, now developing in London, in the action of a few teaching hospitals giving notice of termination of appointments of consulting staffs at smaller hospitals which have been "designated" by the Minister of Health, and demands that Council take suitable action forthwith to end this practice.

Selection of Specialists: Senior Hospital Medical Officers

Motion by PRESTON: That this meeting deprecates the arbitrary action taken by the regional hospital boards in assessing the status of the medical staffs of hospitals.

Motion by READING: That this meeting views with concern the creation of a body of senior hospital officers, without right of appeal against their assessment to an independent tribunal.

Motion by GATESHEAD: That tuberculosis medical officers of standing and experience should be classified as specialists and not as senior hospital officers.

Motion by DERBY: (i) That an intermediate grade should be created between senior hospital medical officers and that of specialists, to include medical superintendents who are not already graded as specialists; (ii) that the salary of this grade range between £1,500 and £2,500.

(Further Motions and Amendments will appear in next week's Supplement)

Association Notices

Diary of Central Meetings

JUNE

- 15 Wed. Coroners Acts Committee, 2 p.m.
- 16 Thurs. Dermatologists Group Committee, 11.30 a.m.
- 16 Thurs. Group of Dermatology Conference, 2 p.m.
- 21 Tues. Conference of Anaesthetists Group, 2 p.m.

Branch and Division Meetings to be Held

KENSINGTON AND HAMMERSMITH DIVISION.—At Kensington Town Hall, Tuesday, June 14, 8.30 p.m. Film: "The Sulphonamides." Members of Westminster and Holborn and Chelsea and Fulham Divisions and non-members in all three areas are invited to attend.

KENT BRANCH.—At Metropole Hotel, West Leas, Folkestone, Thursday, June 16, 12.15 p.m. Annual general meeting.

MACCLESFIELD AND EAST CHESHIRE DIVISION.—At Macclesfield General Infirmary, Sunday, June 12, 12 noon. Instruction of Representative to Annual Representative Meeting; consideration of proposed dissolution of Lancashire and Cheshire Branch and the formation of a "Merseyside" Branch and a "Manchester" or "Lancashire and East Cheshire" Branch.

MID-ESSEX DIVISION.—At Hoffmann Engineering Works, Chelmsford, Wednesday, June 15, 2.30 p.m. Dr. Alan Heard: "What is Industrial Medicine?" To be followed by a tour of the works.

ROCHDALE DIVISION.—At Rochdale Infirmary, Friday, June 10, 8 p.m., annual general meeting. Election of officers and instruction of representative.

SUSSEX BRANCH.—At Warnes Hotel, Worthing, Wednesday, June 15, 1 p.m., annual general meeting and luncheon.

VISITING THE U.S.A.

The Secretary of the Association will be glad to learn if any medical practitioner in this country expects to visit the United States of America during the last week of October.

LONDON SATURDAY JUNE 18 1949

THE SPLEEN AND SPLENECTOMY*

BY

RONALD BODLEY SCOTT, M.A., D.M., F.R.C.P.

Assistant Physician, St Bartholomew's Hospital; Physician, Woolwich Memorial and Surbiton General Hospitals

It is a melancholy reflection that Galen's only aphorism to remain in common currency after 1,800 years is his observation that the spleen was an organ full of mystery. Even to-day its functions in the healthy body remain in part mysterious and its structure matter for argument; but, if physiologists and anatomists still wrangle, the last ten years have enlarged the clinicians' understanding of the spleen in disease and have enabled them to define more exactly the indications for its removal. It is of these clinical aspects of disturbed splenic function and of the value of splenectomy in its correction that this paper treats. Our knowledge of these matters is built on the foundations laid by Frank (1916, 1917), Eppinger (1920), and Naegeli (1940), but its practical application is derived largely from the observations of American haematologists, and in particular of Doan and Dameshek.

Anatomy and Physiology

The spleen may be regarded as a vast lymph node in which, among other specialized circulatory arrangements, the lymph sinuses are replaced by venous sinuses. It consists of a medulla in which are set the Malpighian corpuscles, globular aggregations of lymphocytes disposed around a central arteriole; it is enclosed within a fibrous capsule and scaffolded by fibrous trabeculae with a feltwork of reticulin fibrils. The organ is contractile, and along the verges of the venous sinuses are arranged elements of the reticulo-endothelial system, histiocytes, and undifferentiated mesenchymal cells. The intimate vascular anatomy of the spleen is still uncertain: some believe that the circulation is entirely enclosed within vessels (Knisely, 1934-5, 1936); some that there is no continuity from artery to vein, but that arterial capillaries open into the spongework of the splenic pulp, which in turn drains into the venous sinuses (MacKenzie, Whipple, and Wintersteiner, 1941); and some that there is a double circulation, a closed system in whose walls are pores which allow escape into and return from the surrounding pulp (McNee, 1931).

Whatever the exact nature of the spleen's circulatory arrangements, the organ is well designed to play the part of a reservoir for blood cells, a function postulated 240 years ago by Leeuwenhoek (1708) and established by the well-known researches of Barcroft (1925). In foetal life the spleen is engaged in the genesis of blood cells, but, although some lymphocytes and monocytes are normally of splenic origin, in adult life it resumes haemopoietic

activity only in certain pathological states. Its large complement of reticulo-endothelial cells ensures the spleen's co-operation in the many complex, and often obscure, activities of this system.

These reservoir, haemopoietic, and reticulo-endothelial functions, although clearly of great importance in the body's economy, have not the clear-cut clinical significance of those of the next category. These are concerned with the regulation of the cellular composition of the circulating blood. Although there is no evidence that the spleen takes an active part in the destruction of red blood cells, its removal is followed by a decrease in urobilinogen excretion, which suggests that it removes effete erythrocytes from the circulation. After splenectomy the red blood cells become thinner and more resistant to hypotonic salt solutions, "target cells" appear, and Howell-Jolly bodies and Cabot's rings may be found (Singer, Miller, and Dameshek, 1941).

It may be concluded that the spleen normally increases the thickness of erythrocytes passing through it, that it forms a cemetery for defunct red blood cells, and that it exerts some control over the maturation of erythroblasts, particularly of that phase at which the nucleus is shed. Splenectomy is followed by an increase in the peripheral leucocyte and platelet counts. The former rises to between 15,000 and 20,000 per c.mm., and although the neutrophils commonly share in this increase it is mainly due to a lymphocytosis. The platelet count may reach 1,000,000 per c.mm. The explanation of neither phenomenon is certain: there is no evidence that leucocytes or platelets are normally destroyed by the spleen; the organ must either control delivery of these elements from the bone marrow or exert an inhibitory influence on their formation.

Indications for Splenectomy

This brief review of the spleen's functions must serve as an introduction to the subject of splenectomy. First, two general indications, unrelated to functional disturbance, may be dismissed. The necessity for operation in spontaneous or traumatic rupture is obvious: this gross surgical accident is seldom the concern of the physician, but it is well to recall the special liability to spontaneous rupture of the enlarged spleen in glandular fever (Attlee, 1932; King, 1941; Darley, Black, Smith, and Good, 1944; Davis, Macfee, Wright, and Allyn, 1945; Smith and Custer, 1946). Splenic tumours are almost invariably part of a neoplastic process systematized throughout the lympho-reticular tissue and thus do not constitute an indication for splenectomy; occasionally cysts may require excision.

*A lecture delivered to the Ulster Medical Society on March 3.

FIG. 1.—Transfusion requirements in identical twins with Mediterranean anaemia. The effect of splenectomy is shown in one. (After Govan, 1946.)

Of particular interest to the physician are the various disturbances which may be attributed to exalted splenic function. A resumption of haemopoietic activity occurs in several diffuse obliterative diseases of the bone marrow: it is seen in metastatic carcinoma, in osteosclerosis (Albers-Schönberg), and, particularly and most often, in myelosclerosis in which there is a replacement of normal blood-forming marrow by fibrous tissue and fine trabeculae of new bone. The spleen in this disorder undergoes myeloid transformation and may reach massive proportions; it is virtually the only haemopoietic tissue remaining, and for this reason its excision is strongly contraindicated. The diagnosis of this disease thus assumes some importance: in addition to splenomegaly, the features are anaemia of the leuco-erythroblastic type and a marrow of reduced cellularity on puncture; a trephine biopsy of the sternum may be required before the diagnosis is assured.

Exaltation of the reticulo-endothelial functions of the spleen provides no definite clinical syndrome; it is in its effect on the circulating blood that hypersplenism becomes

of great importance. This may result in anaemia, in thrombocytopenia, or in leucopenia, or in any combination of these changes.

Splenectomy in Anaemia

The value of splenectomy in some forms of haemolytic anaemia has long been appreciated, but the relation between splenic activity and the various haemolytic states is a matter of complexity. There is first a group of haemolytic anaemias in which the fundamental abnormality is a congenital and often inherited deformity of the red blood cell. The most common of these is familial acholuric jaundice, in which the erythrocytes have a shape approximating to the spherical. These spherocytes are retained selectively by the spleen and there destroyed in numbers often sufficient to lead to anaemia and haemolytic jaundice.

The spleen's activity in this disease must be regarded as normal but one which has a vicious effect on the organism because large numbers of the red blood cells, although functionally adequate, are mal-

FIG. 3.—Haemolytic anaemia of unknown cause in a man aged 43.

formed and consequently are removed from the circulation. Splenectomy abolishes excessive haemolysis and usually reduces spherocytosis, for cells passing through the spleen are normally increased in thickness. In sickle-cell anaemia, which presents analogies with acholuric jaundice, splenectomy is curiously and notoriously ineffective. The third anaemia of this type—Mediterranean anaemia—occupies an intermediate position in this respect, and an interesting controlled experiment in which the spleen was removed from one of a pair of identical twins with this disease shows how beneficial the operation may be (Fig. 1) (Govan, 1946).

The second category of haemolytic anaemias is that in which some external factor is responsible for the destruction of red blood cells. This may be a recognizable toxic agent such as lead or one of the sulphonamide drugs, but the present discussion is concerned with those acute and chronic forms of acquired haemolytic anaemia in which no cause is evident. There is reason to believe that many are due to an antigen-antibody type of reaction: in some a haemolysin can be demonstrated in the patient's serum (Dameshek and Schwartz, 1938, 1940);

FIG. 2.—Acquired haemolytic anaemia of unknown causation in girl aged 18. Erythrocyte fragility 0.7-0.45% NaCl. Splenectomy: recovery.

in others the Coombs test provides indirect proof of its presence (Coombs, Mourant, and Race, 1945). Damage to the circulating erythrocytes, falling short of lysis, may be shown by spherocytosis and decrease in hypotonic resistance; in others inclusion bodies within the red blood cells are evidence that they have suffered injury (McFadzean and Davis, 1947). These cells may be adequate for the transport of oxygen, but they are removed and destroyed by the voracious and indiscriminating spleen.

In acquired haemolytic anaemia of this type, where the cause is unknown and therefore insusceptible of control, splenectomy must be recommended if the haemolytic process shows no sign of abating during a period of observation and blood transfusion. Removal of the spleen will remove the organ responsible for destroying damaged red blood cells, and it has been suggested that the haemolysis may be elaborated in the spleen itself. The effect of operation cannot be foretold: it may be dramatically efficacious; it may not influence the process at all; but the patient whose condition is deteriorating should always be given the chance. Figs. 2-5 show instances of this disease in which the result of splenectomy varied from complete and immediate remission to utter ineffectiveness.

The third group of haemolytic anaemias are those secondary to a splenomegaly which may be of almost any nature: there are records of this combination in lymphatic leukaemia (Marchal, Dany, and Grupper, 1934; Singer and Dameshek, 1941; Feldman and Yarvis, 1944), Hodgkin's disease (Holler and Paschke, 1927; Kwaszewska, 1931; Bensis and Gouttas, 1934; von Braitenberg, 1937-8; Slot, 1938; Stats, Rosenthal, and Wasserman, 1947), sarcoidosis (Crane and Zetlin, 1945), Gaucher's disease (Mandelbaum, Berger, and Lederer, 1942), kala-azar (Burchenal, Bowers, and Haedicke, 1947), and tuberculous splenomegaly (Engelbreth-Holm, 1938). In many instances the haemolytic anaemia has been cured by splenectomy. The cause of this form of haemolysis is uncertain: in some instances it seems likely that red blood cells have become sequestered in the labyrinthine pulp of a vast spleen, there undergoing lysis; it has been suggested that the enlarged spleen elaborates a lysis or produces in

FIG. 4.—Acquired haemolytic anaemia of unknown cause in a woman aged 31. Erythrocyte fragility 0.5-0.45% NaCl. Failure of splenectomy.

greater measure its normal lysolecithin (Dameshek and Miller, 1943). Circumstances dictate the desirability of splenectomy: in a slowly progressive disorder in which the major disability is due to haemolytic anaemia it may well be justifiable; in a rapidly advancing leukaemia it would clearly be injudicious.

Figs. 6-8 illustrate instances of haemolytic anaemia associated with the splenomegaly of Hodgkin's disease, reticulosarcoma, and lymphatic leukaemia. In the first the patient presented with haemolytic anaemia and splenomegaly; splenectomy relieved all symptoms, but the excised organ showed the changes of Hodgkin's disease (Fig. 6). He remained in good health for 4½ years, when haemolytic anaemia recurred and he died from renal failure due to amyloidosis three months later. In this patient splenectomy resulted in nearly five years of normal existence. The anaemia in the second patient was of subacute evolution and the haemolytic process was controlled by splenectomy, although she died three months later from the underlying disease (Fig. 7). The patient with lymphatic leukaemia had four haemolytic episodes over a period of five years, the last proving fatal (Fig. 8); haemolysis was controlled in the first three by irradiation of the spleen and repeated blood transfusion. In the light of subsequent events splenectomy during the first episode might have been justifiable.

Splenectomy in Thrombocytopenia

Idiopathic thrombocytopenic purpura has long been recognized as a condition in which splenectomy is often

FIG. 5.—Acquired haemolytic anaemia of unknown cause in a woman aged 57. Erythrocyte fragility 0.55-0.45% NaCl. Splenectomy was followed by remission, but fatal relapse occurred.

followed by a rise in the platelet count and by relief of the haemorrhagic symptoms. The relation of thrombocytopenia to the haemorrhagic tendency is as yet an unsolved problem, but it is true to say that a reduction in platelets below 100,000 per c.mm. is usually attended by spontaneous haemorrhages, which as a rule cease when the platelet count rises to normal levels.

The part played by the spleen in idiopathic thrombocytopenic purpura has been the subject of much debate and there are still two opposed doctrines—the one holding that this organ is engaged in excessive destruction of platelets, the other that it exerts an inhibitory effect on platelet formation in the bone marrow. Injections into animals of extracts of spleens excised in this disease have an inconstant effect in inducing thrombocytopenia; the observations are inconclusive (Troland and Lee, 1938; Tocantins, 1939; Major and Weber, 1939; Pohle and Meyer, 1939; Hobson and Wits, 1940; Rose and Boyer, 1941). Histological evidence of excessive platelet destruction in the excised spleens is usually lacking, although there are claims to the contrary (Nickerson and Sunderland, 1937).

Thrombocytopenia may occur independently of the spleen's action: in acute leukaemia, aplastic anaemia, and carcinomatosis of bone it is secondary to changes in the bone marrow; it may be allergic in origin (Squier and Madison, 1937); it may be the result of idiosyncrasy to such drugs as "sedormid," gold, or arsphenamine. Precise diagnosis is clearly an essential preliminary to splenectomy. Examination of the bone marrow will exclude leukaemia and similar conditions. Schwartz (1945) has claimed that an increase in marrow eosinophils is associated with a particular tendency to spontaneous remission and has suggested that these cases have an allergic origin. His claims lack confirmation (Diggs and Hewlett, 1948), and the diagnosis of allergic thrombocytopenia must remain a matter of diffi-

culty; it is undoubtedly rare. A careful history will allow separation of the cases due to drug idiosyncrasy.

Bone marrow examination has a more positive value in the diagnosis of splenic thrombocytopenia: in this condition the megakaryocytes, the parent cells of the platelets, are plentiful, although it is uncertain whether they are more abundant than normal (Dameshek and Miller, 1946; Diggs and Hewlett, 1948). Although numerous, they are less mature than normal and show little or no evidence of active platelet formation. Within twenty-four hours of splenectomy coincident with the thrombocytosis in the blood, the megakaryocytes show a great increase in platelet formation and in maturity. These observations seem to indicate an inhibitory effect of the spleen on thrombocytopoiesis and to dispose of the hypothesis of excessive splenic destruction of platelets.

Granted the clinical picture of idiopathic thrombocytopenic purpura and the absence of other possible cause splenectomy is indicated when there is no sign of spontaneous remission and when the bone-marrow examination shows plentiful megakaryocytes but depressed platelet formation.

Two recent cases (Fig. 9) illustrate the satisfactory increase in platelet count that may be expected if these criteria are observed, but they stress another difficulty in the treatment of this disorder. Case 1 was relieved of all tendency to bleed and has remained well for over a year; in Case 2 there has been no change in the haemorrhagic state.

In addition to the familiar primary splenic thrombocytopenia, a similar condition may occur secondary to splenomegaly of many kinds: it has been noted, for example, in Hodgkin's disease, Gaucher's disease, congestive splenomegaly, and reticulosarcoma. The changes in the bone marrow are identical with those of the "primary" variety. In some instances the haemorrhagic state is of such intensity that it constitutes the main disability. In such circumstances it may be justifiable to recommend splenectomy, for it will often ensure additional months or years of comfortable existence, although it cannot of course influence the final outcome of the underlying disorder.

Fig. 10 shows the effect of splenectomy on the platelet count in two examples of this secondary type of hypersplenic thrombocytopenia. The cause of splenic enlargement was lymphoid follicular reticulosis and lymphoblastic reticulosarcoma respectively; a similar result has been obtained in a patient with Hodgkin's disease. In all three a disabling haemorrhagic state was satisfactorily controlled.

FIG. 6.—Hodgkin's disease with haemolytic anaemia in a boy aged 14.

FIG. 7.—Haemolytic anaemia secondary to reticulosarcoma of the spleen in a woman aged 58. Splenectomy: remission.

FIG. 8.—Haemolytic anaemia associated with chronic lymphoid leukaemia in a man aged 57.

In the past there has been tacit assumption that thrombocytopenia following medication with such drugs as gold, coarsphenamine, and the sulphonamides was due to a direct toxic effect on the bone marrow. The bleeding tendency usually disappears after the drug is withdrawn, but in two recently reported instances, one following gold Mettler, McBride, and Li, 1948) and one sulphathiazole (Farfel, 1944-5), it persisted and endangered life. In both, the bone marrow was found to contain megakaryocytes in normal or increased numbers, although they were inactive and less mature than normal; in both, splenectomy was followed by a rise in the platelet count to normal and by cessation of bleeding. It may be that removal of the physiological splenic inhibition of thrombopoiesis was enough to restore platelet formation to normal.

Splenectomy in Neutropenia

The effects of the spleen on the leucocytes are less well appreciated than those on the red blood cells and platelets. Rank (1916, 1917) noted a leucopenia in many patients with splenomegaly and the increase in white blood cells

FIG. 9.—Effect of splenectomy in idiopathic thrombocytopenic purpura.

which followed splenectomy. He suggested that the spleen exerted a toxic effect on the bone marrow, which might result in aplasia when it became intense, and proposed the term "aleukia splenica" for the condition.

As in splenic thrombocytopenia, two forms of splenic neutropenia can be recognized. Although the first case was reported by Reissman (1938), Wiseman and Doan (1939, 1942) must be credited with recognition of the primary syndrome. This occurs most commonly in women between the ages of 30 and 60 years, and is manifest by chronic ill-health with recurrent skin and oral infections. The spleen is usually moderately, sometimes greatly, enlarged. Blood counts show persistent leucopenia, commonly varying between 1,000 and 2,000 per c.cm., with less than 20% of neutrophils; in many there is a moderate thrombocytopenia. The bone marrow is of increased cellularity, and formation of granular cells is unduly active, although mature forms may be scanty.

In many instances splenectomy has been followed by restoration of a normal leucocyte count and disappearance of all symptoms (Muether, Moore, Stewart, and Broun, 1941; Auger, Jobin, and Larochelle, 1945; Langston, White, and Ashley, 1945; Rogers and Hall, 1945; Salzer, Ransohoff, and Blatt, 1945; Hepp and Mallarmé, 1946; Kinsey and Bingham, 1946; Lotz, 1947). In this disorder again there is controversy over the means by which the spleen exerts its effect. Some hold that there is excessive lysis of neutrophils in the organ (Wiseman and Doan, 1939; von Haam and Awny, 1948), describing phagocytosis of granular cells in sections and smears of the

Male, 33 yrs., Lymphoid Follicular Reticulosis: ---

FIG. 10.—Effect of splenectomy on platelet count in two cases of thrombocytopenic purpura due to secondary hypersplenism.

excised spleen. Many have reported non-specific hyperplasia of the organ without evidence of phagocytosis; perhaps the body of opinion favours the view that the spleen controls in some fashion the emission of granulocytes from the bone marrow (Engelbreth-Holm, 1938).

A recently reported instance, which can be matched by a personal experience, illustrates the need for caution (Hattersley, 1947). Both fulfilled all the diagnostic criteria of Wiseman and Doan, but in neither did splenectomy relieve the neutropenia or the tendency to infection.

Secondary splenic neutropenia as an isolated phenomenon is rarer than the analogous thrombocytopenia. It has been most often recorded in Felty's syndrome, wherein rheumatoid arthritis is associated with generalized lymphadenopathy and splenomegaly. Splenectomy has been advocated for this combination (Hanrahan and Miller, 1932; Craven, 1934), but, although the neutropenia is thereby relieved and general health may be improved, the arthritis is seldom affected (Steinberg, 1942). It is justifiable only when disabling symptoms can be attributed to the leucopenia. The operation has even been recommended for rheumatoid arthritis without splenomegaly or leucopenia; it has the support neither of logic nor of experience.

Splenectomy in Pancytopenia

It is not surprising to find that in some instances the action of the spleen is exerted not on one variety of blood cell but on all: in these patients there is anaemia, neutropenia, and thrombocytopenia. The syndrome has been given the title of "splenic pancytopenia" (Doan and Wright, 1946, 1947). Two distinct forms of anaemia are encountered in this disorder: in some it is frankly haemolytic, with jaundice, reticulocytosis, and urobilinuria; more often there is little unequivocal evidence of blood destruction, although the daily excretion of urobilinogen is usually above normal. The bone marrow in splenic pancytopenia is of increased cellularity: granulopoiesis is active and megakaryocytes are present in normal numbers, although thrombocytopoiesis is defective; erythropoiesis is normoblastic and unduly active in the haemolytic form of the disease, and in the non-haemolytic variety there is often a predominance of the less mature grades of normoblast, suggesting arrest of the normal process of maturation.

As with other hypersplenic syndromes, primary and secondary pancytopenia has been recognized. In most of the reported primary cases splenectomy has restored the blood to normal and the patient to health. The excised spleen is agreed by most observers to show no more than a non-specific hyperplasia. It is a rare disorder, but the following example is characteristic in all respects but the unhappy outcome.

A night watchman aged 55 was admitted with symptoms of anaemia and with splenomegaly. There was a normocytic anaemia with a haemoglobin level of 50% (Haldane); leucocytes numbered 2,000 per c.mm., of which 32% were neutrophils; platelets totalled 77,000 per c.mm. There was no evidence of excessive haemolysis. Sternal puncture showed a very active bone marrow. Splenectomy resulted in a rapid rise of leucocytes to 14,500 and of platelets to 368,000 per c.mm. The spleen showed a non-specific hyperplasia; the liver was normal at operation and on biopsy. Unfortunately he died on the tenth day after operation from a secondary haemorrhage from the wound.

FIG. 11.—Splenectomy in secondary splenic pancytopenia in a woman aged 34. Reticulum-cell medullary reticulosis.

Secondary splenic pancytopenia is not uncommon in its minor grades: it is the rule in congestive splenomegaly and occurs with many other forms of splenic enlargement. It does not often justify splenectomy, although satisfactory results have been reported in Gaucher's disease (Mandelbaum, Berger, and Lederer, 1942). The blood changes in kala-azar can best be explained by secondary hypersplenism of this type (Cartwright, Chung, and Chang, 1948), and, although chemotherapy will usually effect a cure, cases resistant to treatment and sometimes associated with a haemolytic anaemia occur. Several recent reports have stressed the value of splenectomy in such patients (Burchenal, Bowers, and Haedicke, 1947; Morton and Cooke, 1948).

In some of the less common proliferative diseases of lympho-reticular tissue secondary splenic pancytopenia is a prominent feature. This is so in histiocytic medullary reticulosis (Bodley Scott and Robb-Smith, 1939), and in one instance a satisfactory remission of some months was secured by splenectomy (Asher, 1946). A recent example of a related condition has responded in like manner.

A married woman aged 34 was admitted with massive splenomegaly and moderate generalized lymphadenopathy. There was thrombocytopenia, neutropenia, and normocytic anaemia without evidence of undue haemolysis. The bone marrow was active. Remittent fever was present. An excised lymph node showed the changes of reticulum-cell medullary reticulosis. The radiotherapist was unwilling to treat her in view of the leucopenia. Splenectomy restored the blood picture to normal and relieved all symptoms. She remains well three months after the operation (Fig. 11).

This mechanism has recently been suggested as the explanation of the puzzling crises of acholuric jaundice (Dameshek and Bloom, 1948). It has long been known that in these "crises de déglobulisation" there is profound anaemia without reticulocytosis but accompanied by thrombocytopenia and leucopenia. The bone marrow may show changes suggesting an arrest of erythroblastic development while granular cells are prominent and megakaryocytes numerous but inactive. Splenectomy at this point is followed not only by rapid repair of the anaemia but by release of granular cells and platelets. The hypothesis that the enlarged spleen, as well as destroying the spherical red blood cells, is exerting a secondary inhibitory effect on bone-marrow function satisfactorily explains this puzzling phenomenon.

The indications for splenectomy in aplastic, or refractory, anaemia are relevant to the topic of splenic pancytopenia if it is allowed that the spleen normally exerts an inhibitory influence on haemopoiesis. The operation has been recommended from time to time for this disease and occasional successes have been recorded. It is the general experience that results are disappointing and the benefit only transient (van Beurden, 1935). The Italian haematologists have recognized an indolent form of aplastic anaemia which they term "progressive myeloid atrophy" (Ferrata, 1939a, 1939b; Cattaneo, 1942, 1946). Its distinction from other forms seems to depend on the speed of its evolution, but good results have been reported from splenectomy in some patients. Occasional examples are seen in which a haemolytic element is clearly present, and this constitutes an indication for operation; some would extend it to those whose bone marrow contains megakaryocytes, especially if they are inactive, and shows some evidence of erythroblastic regeneration (Estren and Dameshek, 1947).

Splenectomy in Congestive Splenomegaly

The problem of splenectomy in congestive splenomegaly (Banti's syndrome) is of a different order. Observations at the Presbyterian Hospital in New York have shown that the splenomegaly is here due to obstruction to the venous outflow from the organ (Whipple, 1937, 1945; Rousselot, 1940; Thompson, 1940). It is in fact synonymous with obstruction to, and hypertension in, the portal venous system, apart from occasional examples due to thrombosis of the splenic vein. In 70% the cause is cirrhosis of the liver; in the remainder various extrahepatic obstructive lesions are present. The main danger lies in the tendency to rupture of the dilated venous collaterals at the lower end of the oesophagus.

It has already been pointed out that secondary hypersplenism is common in congestive splenomegaly, but it is seldom of a degree to demand operation. Splenectomy is curative in thrombosis of the splenic vein, but where the obstruction is of the portal trunk or its branches within the liver this operation has little effect on portal hypertension. The improvement occasionally noted must be attributed to the relief of secondary hypersplenism, and perhaps to the removal of the splenic contribution to the portal blood flow, which is said to amount to 40% of the total. Splenectomy cannot be regarded as a rational or effective treatment for congestive splenomegaly, unless due to thrombosis of the splenic vein. The operations devised to by-pass the obstruction by shunting the venous flow via the splenic vein into the left renal vein, or by anastomosing the portal vein and the inferior vena cava, are more logical and more promising (Blakemore and Lord, 1945; Learmonth and Macpherson, 1948).

Conclusion

This review has attempted to show that, with the exception of two mechanical disturbances—rupture and thrombosis of the splenic vein—the indication for splenectomy is an imbalance of the delicately poised equilibrium between the haemopoietic functions of the bone marrow and the inhibitory and haemolytic activities of the spleen. This may arise from a primary splenic disorder or be secondary to many forms of splenomegaly; it may be due to hypoplasia of the bone marrow or to the production of malformed red blood cells; it may affect the erythrocytes, the granular cells, or the platelets, severally or concurrently. In every variety splenectomy may restore the blood to normal and the patient to health.

I am grateful to my colleagues at St. Bartholomew's Hospital for permission to refer to patients who have been under their care.

AN OPERATION FOR THE TREATMENT OF STRESS INCONTINENCE

BY

WILFRED SHAW, M.D., F.R.C.S., F.R.C.O.G.

Surgeon in Charge, Obstetrical and Gynaecological
 Department, St. Bartholomew's Hospital; Gynaecologist,
 St. Andrew's Hospital, Dollis Hill

Although most cases of stress incontinence are seen in patients who have sustained injury during childbirth, the condition is by no means uncommon in nulliparae and even in young women. Clinically, in the average case the external meatus is patulous and the urethra is prolapsed downwards and forwards, with the result that the external meatus lies below and behind its normal situation.

Anatomical Considerations

Much work has been done by Curtis *et al.* (1939, 1942), and by Von Lüdinghausen (1932), Kalischer (1900), Andina and Hintzche (1946), in particular. The plain muscle sphincter round the internal meatus consists of two series of loops. In one of these, muscle fibres pass behind the internal meatus with the arms of the loops extending upwards and forwards. The other loop passes in front of the meatus with its arms extending posteriorly and with each arm being pierced by the ureter. There is a tendency to describe this sphincter muscle as the "lisso sphincter."

The striated muscle sphincter of the urethra, which is also known as the sphincter urethrae, the urogenital sphincter, and, more recently, as the "rhabdo sphincter," is much more complicated. Some of its fibres pass circularly round the urethra. Other fibres pass from an attachment to the back of the symphysis pubis area backwards to form a loop posteriorly round the urethra. A third group of fibres are looped in front of the urethra and then pass backwards laterally, to be attached to the lateral wall of the vagina. In another group the fibres are looped in front of the urethra to interlace between the urethra and vagina and subsequently merge into the vaginal wall.

There is some evidence that those cases of stress incontinence which develop after anterior colporrhaphy are caused by the division of the nerves which supply the urethral sphincter. My own view of the aetiology of stress incontinence is that most cases are due primarily to damage or to loss of tone of the condensation of endopelvic fascia which lies between the urethra and the anterior vaginal wall, which I have called the post-urethral ligament. This condensation consists of plain muscle tissue and is attached to the pubic rami on each side and to the neck of the bladder above. It forms a firm supporting shelf of tissue. The ligament cannot be displayed at operation except in cases of cystocele of slight degree; for if any form of prolapse of the anterior vaginal wall is well marked the tissues of the ligament are inconspicuous. It is because of this weakness of the ligament that the prolapse develops. In my view the main cause of stress incontinence is weakness of this ligament, although damage to the urethral sphincter or to its nerve supply is a contributory factor. The radiographic findings of downward displacement of the urethra and the neck of the bladder in cases of stress incontinence can be explained in this way.

Surgical Methods

Surgical treatment by the vaginal route has the object of forming a shelf of the para-urethral tissues beneath the urethra, and numerous modifications of this technique are employed. Kelly's method of introducing mattress sutures into the neck of the bladder gives moderately good results. It is well known that stress incontinence is usually cured if prolapse is treated by vaginal hysterectomy or by the modern modifications of the Fothergill operation.

It is also well known that the vaginal methods are not always successful, and various sling methods have been employed. Stoeckel's modification of Goebel's method in which longitudinal strips of rectus fascia were brought down behind the symphysis and sutured together below the urethra, did not give satisfactory results. I learnt this method in Vienna some years ago, but the clinical results were unsatisfactory. In 1942 Aldridge employed a method of bringing down transverse strips of fascia taken from the aponeurosis of the oblique abdominal muscles. Millin (1947) introduced a method whereby the operation is performed retropubically, and modifications have been described by Millin and Read (1948), Marshall (1948), and others. Studdiford (1944, 1945) has described modification of Aldridge's technique. These sling operations are being performed extensively at the present day, and good results are being reported.

In the latter part of 1947 it occurred to me that the problem could be approached in another way, and the idea behind the method which is described below is to replace the weakened post-urethral ligament by a strip of fascia lata taken from the thigh. A preliminary report has already been published (Shaw, 1949).

Selection of Clinical Material.—A very large number of patients suffering from stress incontinence attend the outpatient department of St. Bartholomew's Hospital. It is important to select cases with care, for urgency and frequency of micturition must be distinguished from stress incontinence. The patient should be made to cough while her bladder contains urine, and if the urine can be seen to be discharged from the meatus when the patient coughs stress incontinence is diagnosed. It is also important to exclude neurological causes, and in doubtful cases the patient is referred to a neurologist. Many of the patients have been operated upon on several previous occasions by the vaginal route, and these failures are considered to be particularly suitable for the operation.

Technique

Method of Obtaining the Fascial Strip

The patient lies on her left side with the right knee flexed. An incision 7 in. (17.5 cm.) long is made from the lateral epicondyle of the femur, and the fascia lata is exposed by dissecting the fatty tissues from the fascia. A strip of fascia lata is then taken, not less than 6 in. (15 cm.) and not more than 7 in. long. It is shaped so that it is 1½ in. (3.75 cm.) in diameter in the middle and decreases at each end to a diameter of ½ in. (0.8 cm.) (Fig. 1). The fascial strip is placed upon a gauze pad soaked in warm saline, and the cut edges of the fascia lata are brought together by means of three mattress sutures followed by a long continuous suture. The skin incision is closed with clips. As a general rule

FIG. 1.—The strip of fascia taken from the fascia lata is 1½ in. broad in the middle, tapering to ½ in. at each end, and is 6 in. long.

FIG. 2.—The incisions in the vaginal wall. A midline incision starts about $\frac{1}{4}$ in. away from the urethral meatus. An incision is made on each side from the meatal end of this incision.

there are only one or two small vessels to ligate, and the operation can be easily completed within ten minutes. In no case has there been infection of the wound or the development of a haematoma. Most patients complain of pain in the wound for two or three days after the operation, but no patient has complained of inconvenience of any sort after being up and about.

Dissection of the Urethra and Neck of the Bladder

The patient is placed in the lithotomy position and a Sims speculum is introduced into the vagina. In the group of cases operated upon the cervix could only rarely be pulled down as far as the vaginal orifice. Consequently the following procedure was adopted.

Lane's tissue forceps are placed on the anterior vaginal wall in the midline, about $\frac{1}{4}$ in. (0.3 cm.) above the meatus, and another Lane tissue forceps is attached to the anterior vaginal wall, again in the midline, as high as possible above the neck of the bladder. A midline incision is now made, extending from a point about $\frac{1}{4}$ in. above the meatus to the Lane tissue forceps placed on the upper part of the anterior vaginal wall (Fig. 2). On each side a lateral incision is then made at the end of the incision near the meatus, and the lateral incisions extend outwards towards the pubic rami.

The next step is to dissect away the two triangular flaps marked out by these incisions. The dissection must be made with a scalpel, except laterally, where the separation can be made with the help of a piece of gauze wrapped round the finger. If the correct plane of cleavage is reached it is rare for severe haemorrhage to be encountered. The haemorrhage can be controlled to some extent by injecting oxytocin into the tissues in the neighbourhood of the crura of the clitoris. The dissec-

tion exposes the urethra along the whole of its length together with the neck and base of the bladder (Fig. 3).

Fixation of the Fascial Strip to the Urethra

The fascial strip is now held transversely. The middle of the upper margin of the strip is then sutured to the ring of vaginal wall, $\frac{1}{4}$ in. thick, which remains around the external meatus (Fig. 4). It is customary to introduce three sutures. At no time is the sling sutured to the muscle tissue of the urethra itself. Next, the posterior edge of the sling is sutured to the neck of the bladder, to the upper margin of the post-urethral ligament, and in some cases to the vaginal wall as high up in the vagina as possible. This part of the operation is of fundamental importance, for it is intended that the sling shall support the urethra along the whole of its length, together with the neck of the bladder. If it is found possible to mobilize the bladder from the front of the cervix the upper edge of the sling is sutured to the cervix itself.

Attachment of the Lateral Ends of the Fascial Strip

Much preliminary work was carried out on the anatomy of the symphysis pubis area, and plaster models of the bones were made. It seemed that the most suitable inclination of the sling would be obtained if holes were drilled in the pubic bones just below the attachment of the adductor longus tendons. The method of suturing the ends of the sling to the rectus muscles above the pubis, following the course described by Price (1933), was discarded. The next question to consider was the method of approach to the bones. Initially, a curved incision was made through the skin of the mons with its convexity directed upwards to enclose the clitoris. It was found to be a simple matter to incise the soft tissues down to the level of the tendinous tissues attached to the bones; but haemorrhage was found to be troublesome, and it was necessary to divide the suspensory ligament of the clitoris. Nevertheless, an excellent approach is obtained by this method. There are, however, certain disadvantages. Complete haemostasis may be almost impossible, and it was found necessary to leave a small rubber drain when this incision was made. Another disadvantage is that the lymphatic drainage of the vulva is cut off so that the lower flap becomes swollen, and this happens particularly often in elderly patients.

Another method which was employed on one occasion was to make an arched incision below the clitoris through the tissues which lie internal to the labia minora. The exposure obtained is unsatisfactory, although the operation is relatively bloodless. This method of approach was not repeated.

A third method of approach is to make curved incisions on the outer side of the labia majora at a level which allows the drill-holes to be made just below the attachment of the adductor longus tendon. It is found in practice that there is much variation in the development and vascularity of the adductor muscles which are attached below the level of the adductor longus. The incision through these muscles should be made transversely. It is, however, by no means easy always to expose the pubic bone sufficiently medially to allow the drill-holes to be made near the symphysis pubis.

The fourth method of approach is to make the skin incisions on the inner sides of the labia majora. This method of approach is the one being practised at the moment. It has the obvious disadvantage that a considerable thickness of tissue must be cut through before the bone is exposed. It has, however, so many other advantages that it is the method which is recommended.

One of the most important parts of the operation is to open up the retropubic space on each side lateral to the urethra. It is possible to separate the pubo-coccygeus muscles from their attachment to the pubic bones with the finger, but the method should be regarded with disfavour. It is essential to cut through the pubo-coccygeus muscle near its anterior attachment with a scalpel. The scalpel should be introduced lateral to the urethra and a vertical incision about $\frac{1}{4}$ in. (1.25 cm.) long made through the pubo-coccygeus tendon. As the patient is lying in the lithotomy position there is no risk of injury to the bladder, and troublesome haemorrhage is rarely seen if a scalpel is used. A finger is now introduced through the scalpel incision and the retropubic space opened up. The

FIG. 3.—The lateral flaps are dissected away and the urethra and the neck of the bladder mobilized. The diagram shows the position of the incisions made through the pubo-coccygeus muscle on each side of the urethra.

FIG. 4.—The fascial lata strip sutured into position. The upper margin of the strip is stitched to the circular ring of vaginal wall left near the meatus. The sutures are not passed through the muscle wall of the urethra. At the other side of the fascial lata strip the sutures are introduced between the fascial lata and the front of the cervix. If the bladder cannot be sufficiently mobilized this part of the fascial lata strip is stitched both to the post-urethral ligament and to the anterior vaginal wall.

vertical incision is then made through the skin of the labium majus. The incision through the skin is carried down until the tendinous and muscular tissues are reached. These latter tissues are cut through transversely until the bone is exposed. An assistant now introduces his finger into the retropubic space and a drill-hole is made through the pubic bone with a Hudson brace and drill. It is important to use a drill nearly $\frac{1}{2}$ in. in diameter. It is possible to determine with a fair amount of precision the degree to which the bone has been drilled, and the assistant says at once when the drill emerges into the retropubic space. There seems to be little risk of bladder injury if ordinary care is taken. A special pair of curved forceps is now introduced into the skin incision, passed through the drill-hole, and then made to appear through the incision in the pubo-coccygeus tendon. The appropriate end of the fascial sling is now introduced into the end of the forceps and the forceps withdrawn so that the end of the sling appears through the skin incision in the labium majus.

At this stage it is necessary to introduce a self-retaining catheter, because the external meatus is drawn upwards as soon as the other end of the sling is passed through the drill-hole of its appropriate side, after which there may be great difficulty in finding the external meatus.

The next step is to incise the pubo-coccygeus of the opposite side, to open up the retropubic space, to make a corresponding skin incision through the labium majus, and to make a drill-hole as before. The free end of the sling is now drawn through the drill-hole.

If the two ends of the sling are pulled outwards it can be seen how the broad supporting hammock of the sling draws up the urethra and also brings the urethra forwards towards the symphysis pubis (Fig. 5). The amount of tension required is relatively easy to determine, for the catheter in the urethra indicates the direction in which the urethra is lying.

The next stage of the operation is to repair the anterior vaginal wall. It may be necessary to excise redundant vaginal tissue, and it is not always easy to obtain good apposition in the area around the external meatus. The final steps of the operation consist in suturing the ends of the sling with catgut sutures to the tendinous tissues in the vicinity of

FIG. 5.—Showing the mode of action of the strip of fascia lata. It pulls the urethra and the neck of the bladder forwards and at the same time draws up the meatal end of the urethra.

the bore-holes. Subsequently the redundant ends of the sling are excised, the tissues exposed in each of the skin incisions impregnated with a powder of penicillin and sulphathiazole, and the skin incisions closed with catgut sutures.

Critical Analysis of the Technique

The method would probably not have been employed before the discovery of antibiotics and the sulphonamides, for the risk of the operation is clearly the development of osteomyelitis. Every effort has been taken to ensure asepsis. Penicillin powder is distributed liberally over raw surfaces before the incisions are closed, and all patients have been subjected to penicillin therapy prophylactically for three days after the completion of the operation. No case of osteomyelitis has developed. Nevertheless, probably because of failure to ensure complete haemostasis, three cases of mild suppuration in the pubic wounds arose. Unless haemostasis seems to be absolute a small rubber drain should always be introduced into the skin incision.

It may be argued that the fascial strip acts as a foreign body and may be a source of persistent sepsis if the area becomes infected. This has not happened. It may also be argued that the fascial strip becomes replaced by fibrous tissue so that in time the supporting effect of the sling is weakened. This has not happened in any case, although the first operation was performed more than a year ago.

Similar remarks apply to the other sling operations, for it is difficult to believe that the end of the fascial strip of the Aldridge operation receives any blood supply from its abdominal attachment. Moreover, there is good reason to believe that the tissues of the fascia lata sling act as an organizer to the replacing fibroblasts, which themselves become similar to the cells of tendinous tissue. In favourable cases the whole operation can be completed in forty-five minutes, and none of the patients has developed shock and in no case has there been severe bleeding.

Nevertheless, modifications have been tried. It was found to be an extremely simple procedure to expose the obturator foramen and to introduce the special curved forceps through the foramen to appear through the vaginal wound, and this obturator approach was used in a series of cases. The theoretical advantage is that there is no risk of osteomyelitis in this method. The supporting angle of the sling is, however, unsatisfactory on theoretical grounds. In fifteen cases the obturator approach was made. In twelve cases complete cure of the stress incontinence was obtained, but in three cases the symptom was not completely relieved.

An obvious objection to my method is that a separate incision is made along the thigh. On the other hand, a scar along the thigh does not compare unfavourably with the abdominal scar of the Aldridge operation. To meet this objection slings of tantalum gauze were used in two cases. The end-results were extremely satisfactory, but it was found difficult to pass the ends of the tantalum gauze through the obturator foramen, and the method has not been repeated.

One of the great advantages of the operation is that there is no risk of injury either to the bladder or to the urethra, so that there has been no case of bladder or urethral fistula. Nor, indeed, has there been any haematuria in any of the cases. The wide hammock-like support of the fascia lata strip seems to be theoretically sound. Cases of persistent retention have not been seen, although two or three patients had difficulty in passing urine after being up and about. Experience has shown that it is necessary for the self-retaining catheter to be kept in the bladder for ten days after the operation, because patients have great difficulty in passing urine when they are in bed. Consequently it has been the routine practice to give patients sulphamerazine prophylactically. Some cases have developed cystitis, but in most instances the cystitis has cleared up fairly soon. The worst complication is urgency of micturition, which tends to persist in some cases for several months after the operation. Nevertheless, in only one or two cases have patients been distressed by this symptom.

Results

So far 51 cases have been operated upon. Unfortunately, one patient died. The case history is as follows.

The patient, aged 60, had been married for 44 years, and had had 11 children. She had complained of stress incontinence for four years. Her general condition was fairly good except that her blood pressure was 200/110. A fascial sling operation was performed on July 30, 1948, using the obturator foramen approach, without technical difficulty. It was noticed that the patient was abnormally quiet during the first few days after the operation. On Aug. 5 she became stuporous early in the morning, her tongue was furred, sugar was found in the urine, but Rothera's test was negative. Blood chemistry showed: blood urea 65 mg., blood chlorides 595 mg., and blood sugar 650 mg. per 100 ml. Rothera's test now became weakly positive. She was seen by a general physician and a neurologist, who formed the opinion that the coma was due to a cerebral vascular accident rather than to diabetes, in view of the very high sugar content and the disproportionately low ketosis. The patient died at 3 o'clock that afternoon. A

post-mortem examination was performed by Dr. H. I. Coombs. The signs were regarded as those of diabetes. The operation area was clean, without sepsis or haematoma and with no evidence of injury to the bladder or urethra. The patient would not have died if she had not been operated upon, but there is no reason to believe that the especial character of the operation was the dominant cause of the development of diabetic coma. This fatal case is not included in the series.

Of the other 50 cases, 15 have been operated upon by the obturator foramen approach for the attachment of the ends of the sling, and 35 have been operated upon using bore-holes through the pubic bones. Of the obturator foramen cases, three have not been completely cured of symptoms. The other cases of this group have been cured of their stress incontinence, but in view of the three partial failures the obturator foramen method has been abandoned. Nevertheless, 12 of the 15 cases can be regarded as completely cured, and the three cases that were not completely cured were greatly relieved. The tantalum-mesh cases belong to this group of 15. In both cases an excellent result was obtained, the patients being completely cured.

Of the 35 cases in which drill-holes have been made the results have been satisfactory. One patient, aged 60, developed a stroke six months after the operation, since when she has been incontinent, although at times before she had the stroke she was not completely free from stress incontinence. There is no doubt that this patient was a bad subject for operation, and it was always difficult to decide from the history whether she was suffering from stress incontinence, urgency, or frequency.

In one case the approach to the pubic bones was made by means of a curved incision below the clitoris. This led to the bore-holes being placed low down, and subsequently, although the urethra was well supported by the sling, a slight degree of cystocele developed above this level. Nevertheless, the patient was cured of stress incontinence although she suffered much from urgency. The case is of some interest because there is a tendency to maintain that failure to support the neck of the bladder is the cause of stress incontinence (Muellner, 1949). Except for the patient who subsequently developed a stroke, the 35 patients were all cured of stress incontinence. It was found that the younger patients were completely cured of all their urinary symptoms. The older patients, however, suffered from frequency and urgency for some time after the operation, although these symptoms gradually improved with time.

It is perhaps of some interest to record that the technical problem which caused most difficulty was to decide upon the best method of approach through the skin of the vulva to reach the pubic bones. Each method of approach that was tried had certain advantages, and it was only after very careful consideration that the incisions on the inner sides of the labia majora were selected as the most satisfactory.

In my view the operation should be regarded as an excellent method of treating stress incontinence, particularly in those patients in whom vaginal methods have failed. The technical difficulties are not very great and there seems to be no risk of injury either to the bladder or to the urethra. At first thought the operation of drilling holes in the pubic bones seems to be severe, but in practice it is simple to carry out. Preliminary work with models had shown that the correct inclination of the sling can be obtained only if the pubic bones are drilled. It was felt from the beginning that the inclination of the sling was not the best possible; the ends of the sling were brought through the obturator foramina, but as the first few patients operated upon in this way were relieved of their symptoms the method was employed for a small series of cases. The results, however, were not satisfactory in all cases and the method has been abandoned.

STEATORRHOEA AND GLOSSITIS AFTER ILEOCOLOSTOMY

EFFECT OF SYNTHETIC VITAMINS OF B COMPLEX, AUTOLYSED YEAST, AND LIVER EXTRACT

BY

ALEXANDER BROWN, M.D., F.R.F.P.S., M.R.C.P.Ed.

Assistant, Muirhead Department of Medicine, and Physician to Out-patients, Royal Infirmary, Glasgow

Pantothenic acid and inositol have for many years been recognized as members of the vitamin B complex. The former has been shown to be an essential factor for many animal species, in some of which deficiency is associated with ectodermal defects, such as dermatitis and greying of the hair, and with reduced alimentary motility. Inositol is a normal constituent of all animal and plant tissues. The little that is known of its role in animal nutrition suggests that it also is related to the maintenance of ectodermal tissues. The role of both these substances in human nutrition is still unknown.

The case is here described of a man who had an ileocolostomy performed for what was most probably regional ileitis. He later developed steatorrhea and signs of avitaminoses. His symptoms were predominantly alimentary, and the opportunity was taken to observe the effect on them of pantothenic acid and inositol as well as of other synthetic vitamins and vitamin preparations.

Case Report

The patient had apparently been healthy until September, 1935, when, at the age of 21, he developed pain in the right iliac fossa. Laparotomy revealed a swollen terminal ileum and dense adhesions in this region and around the caecum. The appendix was normal. Anastomosis was performed between the lower ileum and the first part of the transverse colon. The exact length of ileum by-passed in this procedure was not recorded, but from subsequent radiological examination it was estimated to be about 24–36 in. (61–91 cm.). He had no symptoms thereafter until about twelve months later he suffered from diarrhoea, nausea, vomiting, anorexia, and abdominal discomfort over a period of about two weeks. Six months afterwards he complained for the first time of a sore tongue, and his mouth felt raw where it was irritated by his dentures. During the next five years, although abdominal symptoms never amounted to more than occasional mild discomfort across the lower abdomen, the glossitis was constantly troublesome, relieved only by repeated injections of liver extract.

Clinical and Laboratory Findings.—When I first saw the patient on July 21, 1945, he was in good general health. His tongue, however, showed general atrophy of moderate degree and was a fiery red at the tip and edges. No significant abnormality was detected in the abdomen. Blood examination revealed: red cells, 4,230,000; haemoglobin, 11.8 g.%; M.C.V., 96 μ^3 ; M.C.H.C., 29%; white cells, 7,600. A test meal showed free HCl. The fat content of the faeces was 46% of dry matter, and balance experiments revealed that he absorbed only 67%

of a daily intake of 50 g. of fat. The glucose-tolerance curve was flat. Radiological examination of the bowel revealed an irregular pattern resembling that often seen in steatorrhea. The ileocolostomy was apparently functioning satisfactorily. The loop of bowel short-circuited by the operation was patent, but was the seat of very marked stasis.

Treatment and Subsequent Course

With his co-operation the patient was closely observed over a period of almost two years. Clinical trials were carried out with the following synthetic vitamins: calcium pantothenate, inositol, folic acid, nicotinic acid, riboflavin, and aneurin. The effects of yeast extract ("marmite") and of a highly purified liver extract ("anahaemin") were also observed. Details of this treatment and the results are presented in the Table.

When the investigation was begun sore tongue had been present without natural remission for over five years. It was then found that a highly purified liver extract was effective, given intramuscularly or by mouth. Yeast extract (marmite) produced similar results, with a threshold of effectiveness at about 4 g. a day. Five courses of oral calcium pantothenate were given, and on each occasion benefit occurred in four days and complete remission of the glossitis within a week. A more rapid effect was obtained with a single intramuscular dose. Inositol on one occasion had an action on the tongue similar to that of pantothenate. Weekly courses of nicotinic acid, of riboflavin, and of aneurin, seriatim and also simultaneously, were without benefit.

Before the investigation the patient suffered mild abdominal discomfort whenever oral symptoms improved. Throughout the investigation calcium pantothenate, which cured the sore tongue, was invariably associated with abdominal colic-like pain. This was so severe as to be incapacitating when a single dose of 100 mg. was given intramuscularly. Oral liver and marmite cured the sore tongue: abdominal pain previously present did not recur while they were being given. Parenteral liver treatment had an effect similar to that of oral pantothenate in aggravating or producing abdominal symptoms. On the occasion when inositol seemed to cure the sore tongue abdominal pain disappeared, but when abdominal pain was the only symptom it was not affected by inositol. Radiological examination of the alimentary tract at the height of abdominal symptoms after the administration of 100 mg. of pantothenate intramuscularly revealed pronounced duodenal spasm and an exceedingly active and irregular spastic small bowel. There was no chemical evidence that calcium pantothenate improved absorption of fat or glucose.

Results of Treatment

Pantothenic Acid.—The uniformity of the response to calcium pantothenate on six occasions during a prolonged period of observation is regarded as justifying the conclusion that it had an effect analogous to that of other known vitamins in their respective avitaminoses. The effects of pantothenate in this man were in some respects similar to those which have been attributed to the vitamin in animals. It had a rapid curative action on his abnormal buccal mucosa (ectodermal tissue) and it increased his intestinal motility. It did not, however, restore to normal the disordered intestinal motility or improve carbohydrate or fat absorption.

Inositol.—Inositol and pantothenic acid have been shown to be related biologically, and their similar actions on the glossitis are interesting in this respect. The fact that inositol did not induce abdominal pain is in keeping with the absence of any specific effect on alimentary motility in animals.

Folic Acid.—Glossitis was not present when folic acid was used effectively in the treatment of abdominal pain. The relation of folic acid to this symptom is obscure, but it is interesting to compare this effect with the beneficial action of the vitamin on the radiological appearances of the small bowel in cases of the sprue syndrome (Darby, 1947; Ferguson and Calder, 1948).

Date	Treatment*	Results	
		Glossitis	Abdominal Pain
1945			
July 21	Before starting treatment	+++	None
" 28	Nicotinic acid, 150 mg./day for 7 days	+++	Vague
Aug. 4	Aneurin, 18 mg./day for 7 days	+++	Vague
" 11	Riboflavin, 6 mg./day for 7 days	++++	None
" 18	Anahaemin, 2 ml. i.m. (single dose)	++++ Healed by Aug. 23; recurred within a week	None; then moderate severe almost daily for 7-8 days
Sept. 1	Nicotinic acid, 150 mg. daily for 7 days	+++	Remained mild
" 8	Aneurin, 18 mg. daily for 7 days Riboflavin, 6 mg. daily for 21 days Marmite, 8 g./day for 21 days	++++ Healed completely in 7 days	Mild: disappeared within 7 days and remained absent until December
" 29	Marmite, 4 g./day for 7 days	Still healed, but relapsed in 4 days	
Oct. 6	Anahaemin, 1 ml./day for 7 days	+++ Healed completely by 7th day	
" 13	Anahaemin, 0.5 ml./day for 7 days	Remained healed until Jan., 1946	None: vague in December
1946			
Jan. 12		+	Slight
" 19		++	Slight
" 26	Calcium pantothenate, 50 mg./day for 4 days	+++ Healed by 5th day; recurred by 10th day	Pain within 48 hours of 1st dose almost daily for 6 days: gradual lessened to 10th day
Feb. 7		++	Vague
" 9	Calcium pantothenate, 100 mg./day for 5 days	++++ Healed from 5th to 14th day; then recurred	Absent. Pain within 4 hours of 1st dose almost daily for 1 day; then less severe
" 23		+	Less severe
Mar. 2	Calcium pantothenate, 100 mg./day for 7 days	++++ Healed from 5th to 21st day; then recurred	Absent. Returned with 48 hours of 1st dose for 12 days almost daily
" 23		+	Less severe
" 30		++	Slight
Apr. 6	Calcium pantothenate, 100 mg. i.m. (single dose)	++++ Improved by 48 hours; almost complete remission for 10 days	None, but extreme within 24 hours; lasted days, then less severe
" 20	Nicotinic acid, 400 mg./day for 14 days	+++	Less severe; gradual diminished
May 4	Nicotinic acid, 50 mg. i.m. every 2nd day (3 doses)	No effect	Slight 2-3 a week
" 18	Calcium pantothenate, 100 mg./day until May 26	++++ Completely healed from May 25 to 28	Vague. Severe within hours of 1st dose; then almost daily
" 30	Calcium pantothenate, 75 mg. (single oral dose)	+	Pain disappeared 29th, but was severe within 6 hours of 1st dose
June 1	Inositol, 37.5 mg./day for 7 days	++ Slight improvement by June 8	Pain disappeared with 48 hours of 1st dose
" 8	Inositol, 75 mg./day for 7 days	+	
" 15	Calcium pantothenate, 100 mg./day for 7 days	+	Absent. Recurred with 3 days; then moderately severe almost daily
" 22	Anahaemin, 2 ml. i.m. (single dose)	Still healed; remained so till July	
Aug. 3	Inositol, 37.5 mg./day for 2 weeks	+++ Marked improvement by 7th day; healed by 14th	Still severe daily
" 10		+	
" 17	Inositol stopped	Healed	Vague
Sept.-Jan. 1947	Liver extract (i.m.) from time to time	Remained healed	Absent
Jan. 25	Folic acid, 15 mg./day for 2 weeks	Still healed	Rarely more than discomfort, or two without mild pain, which gradually increased in December
Feb. 8	Folic acid, 20 mg./day		Daily severe. Rapid improvement. Absent from 5th day apart from mild flatulence
" 15	Folic acid stopped		Flatulence disappeared
" 19			Pain returned. Occurred daily
" 22	Folic acid, 15 mg. i.m.		Complete relief for 3 days; then severe before
Mar. 1	Inositol, 30 mg./day for 7 days		No relief
" 15	Folic acid, 20 mg./day		Complete relief from 4th day

* All treatment is oral unless other method of administration is specified.

In considering the effects of individual vitamins the possible biological interrelationships of inositol, pantothenic acid, and folic acid are important. Investigations on the role of folic acid and biotin were reviewed by Wright and Welch (1943), who confirmed the previous findings. It is evident that utilization of pantothenic acid depends on the availability of the other two substances, at least in the experimental animal; and pantothenic acid seems to induce intestinal synthesis of inositol (Woolley, 1942). The results of these investigations are of course not necessarily applicable to man, but they at least serve to indicate the probable complexity of the problem.

Yeast and Liver Extract.—The beneficial action of these two complex substances might at first sight be explained on the basis of their pantothenic acid content. This is by no means certain, since anahaemin is stated by the makers to contain only about 0.001 mg. per ml., and marmite only about 0.06 mg. per g. Thus 1 ml. of anahaemin per day orally (0.001 mg. of pantothenic acid) was rapidly curative, and 4 g. of marmite daily (0.24 mg. of pantothenic acid) allowed symptoms to recur. On one occasion 76 mg. of calcium pantothenate by mouth failed to cure the sore tongue, and on several occasions the administration of 100 mg. was no more effective than oral anahaemin or marmite, and the improvement was short-lived compared with the long remission which followed oral liver therapy. Finally, the effect of oral liver and of yeast extract on alimentary symptoms was different from that of calcium pantothenate. Admitting the possibility of coincidence and of natural fluctuations in the clinical state, it does seem probable that anahaemin and marmite were effective by virtue of a factor other than pantothenic acid or inositol. The minute amount of this active principle required recalls the activity of folic acid and of vitamin B₁₂ in Addisonian pernicious anaemia and in the sprue syndrome. In this case observations on folic acid did not reveal the scope of its action.

Whatever this active principle is, it seems probable that lack of pantothenic acid was responsible for the glossitis, and that administration of calcium pantothenate repaired this deficiency and stimulated bowel activity. Pantothenic acid deficiency was not responsible for the disordered bowel activity, and when this was stimulated pain resulted. As an alternative explanation it might be suggested that the administration of calcium pantothenate replaces one deficiency and at the same time aggravates other coexisting deficiencies in a manner analogous to the development of beriberi or ariboflavinosis in pellagrins treated with nicotinic acid (Sydenstricker, Sebrell, Cleckley, and Kruse, 1940).

Aetiology of the Defects

In the past, organic disease of the intestine, with or without operative intervention, has been reported in association with defective fat absorption, signs of deficiencies of vitamins of the B group, and macrocytic anaemia. In a review of the literature Barker and Hummel (1939) referred to 51 such cases. Steatorrhoea is not a commonly recorded feature of regional ileitis. Bockus (1945), in reviewing this condition, made only passing reference to occasional avitaminoses and steatorrhoea in the untreated case. Nor is steatorrhoea a commonly recorded sequel to the operative treatment of this condition; but in stressing the need for a high protein diet and liberal intake of vitamins of the B complex in order to avoid the development of serious nutritional disorders Brown and Donald (1942) gave the impression that such conditions may be more common than is indicated by the available literature.

Conditions such as alimentary and peritoneal tuberculosis and extensive infiltration by lymphosarcoma or lymph-

adenoma may interfere with absorption in a mechanical fashion, but the occurrence of steatorrhoea and deficiency states in association with local disease or stricture is not so readily explained. Whether the effects are due to reduction in the absorbing surfaces or whether there is in addition some other disturbance—e.g., in the bacterial flora—which might interfere with the requirement for optimal absorption is not known. In favour of some additional factor is the observation that massive resection of the intestine in man is compatible with survival and good health. Prioleau (1943) reported such an instance which followed the removal of about 12 feet (3.65 metres) of small bowel and 1 foot (30 cm.) of large bowel. Elman and Read (1945) reported extensive resection of the small bowel and the right half of the large bowel with subsequent gain in weight and normal alimentary function on an unrestricted diet. From a review of 257 cases in which over 6 feet (1.83 metres) of small intestine had been removed Haymond (1935) concluded that resection of over half (11 feet (3.35 metres) in the average individual) was likely to give poor results.

In the present case no bowel was removed and the extent of the disease was relatively small, yet some time after operation, when activity of the disease was no longer evident and when the previously abnormal portion of bowel was found to be patent, steatorrhoea and avitaminoses were well established. It is impossible to be certain that the disease and the ileocolostomy and the subsequent illness were related as cause and effect, but in the past intestinal strictures have been found to cause similar disturbances, which on occasion have been cured by removal of the affected part. Barker and Hummel (1939) described the case of a man aged 56 who developed a megaloblastic anaemia and a sore tongue after ileocolostomy for "non-specific ileitis." The by-passed loop of small bowel and colon was left as an alternative channel for alimentary contents as in the present case.

The clinical and haematological features of sprue were described by Wintrobe (1942) in a patient in whom extensive resection of intestine had been performed. Temporary improvement occurred when at a later date a blind loop of bowel was removed. Watson, Cameron, and Wits (1948) mention the occurrence of megaloblastic anaemia without steatorrhoea following ileo-ileostomy performed to by-pass a subacute obstruction from regional ileitis. The possibility again arises that in some instances at least a factor other than reduction in surface may contribute to the development of deficiencies. A possible mechanism in such circumstances is by the alteration in the bacterial flora. This raises the old idea of "intestinal toxæmia," but in a new form.

Horster (1935) was able to induce anaemia and hepatic damage in dogs by the production of strictures or blind pouches in the intestine, and to prevent these changes by the oral administration of trichlorcresol. In addition he made the interesting observation that intramuscular injection of liver extract ("campolon") was equally effective. Watson *et al.* (1948) showed that in rats the production of blind loops in the small bowel often resulted in macrocytic anaemia which responded to treatment with liver extract (anahaemin). The development of this anaemia appears to be in some way related to dilatation of the loop and stagnation of its contents.

Marrow smears made from rats with macrocytic anaemia showed normal or increased cellularity, with an increase in the proportion of earlier red cell precursors. Although none of these corresponded exactly to the megaloblasts of human pernicious anaemia, in some cells the arrangement of nuclear chromatin was looser than normal and there

was occasionally seen a nuclear pattern approaching that of the typical megaloblast. It is at least possible that in these animals and also in the cases discussed alimentary stasis in the loop led to an alteration in the bacterial flora of the intestine and disturbed the elaboration or utilization of essential vitamins. It is also possible that the liver extracts in experimental macrocytic anaemia, and yeast and liver extracts in the present case, had an effect analogous to that of folic acid and biotin, which have been shown to reverse many deficiencies produced in the experimental animal by sulphaguanidine or sulphasuxidine.

Summary

The case is described of a patient who developed steatorrhoea and persistent glossitis and stomatitis after ileocolostomy for probable regional ileitis. The oral manifestations of the case were controlled on separate occasions by calcium pantothenate given orally or intramuscularly, by inositol given orally, by yeast extract (marmite), and by oral or intramuscular administration of a highly refined liver extract (anahaemin).

Calcium pantothenate was effective against the glossitis but invariably aggravated abdominal symptoms, particularly when given intramuscularly. Anahaemin given parenterally produced abdominal pain in less degree. Given by mouth, anahaemin, marmite, and also inositol cured the sore tongue but did not provoke abdominal discomfort. Folic acid relieved the colic, but its action on the tongue could not be determined because glossitis was not present at this time. Neither fat absorption nor glucose absorption was improved by the administration of calcium pantothenate. Nicotinic acid, riboflavin, and aneurin had no effect on the glossitis or on the abdominal symptoms.

It is suggested that the action of the yeast and liver extracts was due not to their content of pantothenic acid but to the presence of some other factor or factors which restored existing deficiencies in a more balanced manner, leading to improvement in both oral and alimentary disturbances.

The possible mechanism of the development of the steatorrhoea and the associated avitaminoses is discussed, and it is suggested that alteration in alimentary flora and consequent reduction in the availability of essential factors may be at least partly responsible.

I am grateful to Professor L. J. Davis for his advice in the preparation of this paper; to British Drug Houses, Ltd., and the Marmite Food Extract Co., Ltd., for information regarding pantothenic acid content of anahaemin and marmite respectively; and also to Dr. F. Wrigley, Director of Medical Research, Roche Products, Ltd., for providing the calcium pantothenate and inositol used in this investigation.

Since local health authorities are having difficulties in providing ambulance services, the Ministry of Health has asked hospital boards and management committees to review their arrangements for calling ambulance services, to see whether fewer calls can be made. The greatest increase in calls has been for sitting cases taken by car to and from out-patient departments. The Ministry would like hospitals to hold clinics at times that fit in with the local bus services, and to arrange for out-patients living near together to attend for treatment at about the same time. The circular also points out that patients, even stretcher cases, can be comfortably conveyed long distances by rail instead of by ambulance or

THE PROGNOSIS OF CERTAIN HYSTERICAL SYMPTOMS

BY

A. BARHAM CARTER, M.D., M.R.C.P., D.P.M.

Physician to Ashford Hospital, Middlesex

Thirty years ago MacCurdy (1918), discussing the treatment of hysteria, said that any physician with enough sympathy, interest, and common sense could obtain good results in many of these cases. He was referring only to the immediate outcome, and it is now agreed that even without the above requisites most doctors can get rid of a hysterical symptom. The present psychiatric view is that this is not always desirable, nor does it really help the patient, as he or she remains ill-equipped to stand up to the future strains that life is bound to impose.

This report is a simple account of what has happened to a number of patients who showed clear-cut hysterical symptoms, who were treated in a rather superficial way, and who have been followed up from four to six years after discharge from hospital.

Material

One hundred cases presenting various types of hysterical symptom were selected from 212 consecutive cases labelled as hysteria. All were seen either as in-patients or as out-patients in two large civilian general hospitals from 1939 to 1943. The selected cases were followed up from four to six years, to the beginning of 1947.

The selection was made by taking only those cases showing clear-cut, isolated, and easily recognizable symptoms so that the symptomatological prognosis could not be mistaken. The cases not included showed a more diffuse and complicated symptomatology, often with objective and subjective disorders of sensation. Each of the selected cases showed one of the following symptoms: amnesia, aphonia, blindness, fits, paralysis, tremor, or vomiting, and the prognosis was very simply judged on the presence or absence or replacement of this symptom after a given time and on the rapidity and frequency of relapse, if any, during this time.

The follow-up was successful in 90 of these cases, the remaining 10 being untraced. The actual material for study is therefore 100 cases with immediate results and 90 with a follow-up.

Definition.—Hysteria is here used to describe a form of psychoneurosis in which an emotional problem has been wholly or partly avoided by the development of a physical symptom which in itself may be symbolic of the presumably unconscious motivation, thus differing from other

Table Showing Analysis of Cases and Results of Follow-up

Symptom	No. of Cases	Condition on Discharge		Follow-up Results, 1946 (4 to 6 Years after Discharge)		Unchanged (at Work)	Worse	Not T'cd.
		Rec'd	Not Impvd.	Well	Impvd.			
Amnesia ..	23	23	0	17	1	0	2	3

Total ..	100	90	10	66	9	8	7	10

psychoneuroses in which the symptoms are coloured by a fixed or diffuse anxiety or tension, and from malingering in which the motivation is conscious.

Analysis of Cases.—The accompanying Table gives a simple analysis of the cases according to the symptoms

The patients were from 16 to 40 years old; 60 were females and 30 were Service cases. Precipitating factors were present in every case; some were more dramatic than others and a few were fairly difficult to elicit. Loss of memory often coincided with the end of a leave period; loss of voice and loss of power with direct evidence of enemy action; tremor with the sudden realization of fear; and blindness with the sight of something unpleasant or of someone thought dead. Since only the prognosis of symptoms is being considered, no other analysis, such as of previous personality, of family, or of physique, has been attempted.

Treatment

It is generally agreed that if a hysterical symptom is to be removed it can best be done by suggestion, and the following methods were used:

(a) *Direct Suggestion*.—This involved the simple statement that a symptom will disappear and normal function return, followed by an examination and by a command to employ the previous non-functioning part. Alone this was of value only in cases of mild disability, such as aphonia, but was of considerable help as part of other methods of suggestion.

(b) *Indirect Suggestion*.—This implied the ignoring of symptoms such as fits or vomiting either completely or by pointing out that they were unimportant. One part of this method, not sufficiently realized by many, was to refrain from inquiry about the progress of a hysterical symptom.

(c) *Hypnosis*.—There is no need to describe the technique of this form of suggestion, which, although very effective at first, tends to be used less and less by the physician who continues to interest himself seriously in psychoneurosis. It has often been said that the theatrical atmosphere and the unfortunate history of hypnosis have a tendency to produce an unusual state of mind in the doctor practising it.

(d) *Suggestion under Thiopentone*.—This method was used in all severe cases of hysteria and will probably replace hypnosis as the method of choice in suggestion therapy, particularly in general hospitals. The technique of this therapy, although well known to psychiatrists who practise narco-analysis, may be of interest to those physicians who like to do their own psychiatric work so far as is possible.

The patient was usually seen the day before treatment, spoken to about his illness, and thoroughly examined. He was told that his condition was a genuine illness caused by some shock to his nervous system, and that this had caused his brain to lose its normal control over the part of the body affected. He was told that he would regain normal control of all his functions and be well again, that his case was in no way unusual, and that recovery would occur the next day with treatment.

The next day he was, if possible, removed to a single room. The thiopentone was prepared (0.5 g. in 10 ml.); 2 ml. was injected and the patient was told he was feeling drowsy and more relaxed. When he began to yawn or to snore slightly he was told that his ability to move or see or feel was returning, and that he was recovering rapidly. He was then given orders to move the limb and was shown the limb moving, and when normal function was established he was aroused and asked to say how it all happened. Not infrequently there was a rush of emotionally charged memory, with tears, shouts, and vivid descriptions.

The above forms of suggestion treatment were all followed by an important routine. No one was allowed to ask the patient how the affected part was, and full recovery was accepted as a *fait accompli*. Then the patient was given two or three interviews and his or her story was listened to sympathetically, with interest and without haste; and, indeed, more good seemed to come from listening than from talking, as patients often found a more satisfactory solution to their problems without further prompting. Environments often needed changing, but more frequently the patient's assessment of his environment was biased by his own feelings of self-importance, and a change in his approach to such problems was essential. The most difficult emotions

to deal with were resentment and self-pity, and encouragement and stimulation of morale were needed to make many of these people realize that what a man believes of himself is more important than what others think of him.

Analysis of Results

The results have been analysed in the same way as the cases, under the headings of each symptom (see Table).

Amnesia

All the 23 patients showing hysterical amnesia recovered their memory within seven days, 18 of them on the second day with the help of direct suggestion or mild hypnosis. The remaining six were reassured, and were allowed to move freely about the ward and recover gradually without any active intervention. Two cases remained amnesic after six days and were given suggestion under thiopentone with success.

The impression given to the physician was that many of these people had committed some social crime; 12 of the patients were young soldiers absent without leave and were avoiding the consequences of their action. The value of this particular symptom as a protection is obvious enough, and if the patient can be assured of his sanity and the return of his memory it is perhaps better to leave him alone until he feels consciously or unconsciously that he can face his environment. All these patients were men between the ages of 18 and 30 with no previous history of hysterical symptoms—an interesting and well-recognized sex incidence.

Follow-up.—Twenty of these patients were seen again from four to six years later, three being untraced. Of the 10 Service patients, five had been discharged from the Army as psychoneurotic and had received no punishment for their crimes; they had had no active psychotherapy except a sympathetic attitude and a course of training for civilian work. All were well and at work, although their attitude towards life remained mildly resentful. The other five Service patients had been retained in the Army, had fought in France and Germany (two with distinction), and eventually had been discharged well. They were all cheerful and at work, and were rather embarrassed at being reminded of their loss of memory. Of the 10 civilian cases, six had not relapsed, two had relapsed once, one more than once, and one was in a mental hospital suffering from schizophrenia. Of the two difficult cases that took a week to recover, one was the schizophrenic and the other had relapsed with amnesia and had developed a tremor as well.

Aphonia

These 29 patients, 20 of whom were women, all recovered their voices with direct suggestion and without very much difficulty. There was in every case a strong tendency to immediate relapse, but reinforcement of the suggestion dealt with this. A very simple technique was used. The patient was asked if she would like her voice back and was then requested to cough. She was informed that if she could cough she could speak, and the throat was examined firmly, often with the production of gagging and an inarticulate sound. This was gradually transformed into articulate speech by telling her to repeat simple words. Very little else was done for these patients, since the symptom was a minor one and not associated in this series with deep psychological disturbances. They all seemed reasonably well adapted to environment, and many were of the emotionally labile and sensitive type with a tendency to tremor and "nervousness." In 15 of the 20 women the aphonia had followed a catarrhal laryngitis.

Follow-up.—Nineteen of these cases had remained well, although they still confessed to nervousness and sweating and an unreasonable fear of difficult situations. Two had relapsed, with loss of voice persisting up to six weeks following sore throat and laryngitis. Seven cases were difficult to assess; these patients said that they always lost their voice if they became embarrassed, worried, or unhappy. They did not seem to be inconvenienced by this, and always regained it when the trouble had departed. The final impression obtained was that aphonia by itself is a symptom of only mild mental dissociation and has a good prognosis. One case was untraced.

Blindness

Only three cases of blindness were seen, and all in 1941. One was a battle casualty who had seen his best friend decapitated, one a woman who had seen her child burnt to death, and the third a woman whose husband, believed dead, had returned at a rather embarrassing moment. All were treated by hypnosis, recovered, and are now well and happy. A simple explanation was given to each one, but no other psychotherapy except an attempt at softening the blow and uncovering a feeling of guilt in the two women.

Fits

The six cases showing hysterical fits were more difficult to deal with. They were treated by indirect suggestion, no importance being attached to the attacks. When these recurred in the ward the patient was moved gently out of the way and allowed to lie on the floor. With this treatment the attacks became less frequent and less severe in every case, but only two lost the tendency completely. The remaining four replaced the true fits by "black-outs," attacks of vertigo, and "fainting attacks." These four cases seemed to have considerable instability, and were referred to a psychotherapist.

Follow-up.—The two who had improved most in hospital remained well; one committed suicide three years later after in-patient treatment in a mental hospital as a schizophrenic; one had remained partially well and was at work, but complained persistently of black-outs. Two were untraced.

Paralysis

Twenty-three cases of hysterical paralysis were treated by hypnosis before 1942 or thiopentone suggestion after 1942. The cases themselves were interesting because in every one the legs were affected, and in three the arms as well. In 10 cases all limbs were freely movable in bed by the patients' own efforts, but walking was impossible or very difficult.

Immediate treatment produced dramatic recovery in 15 cases. The remaining eight were treated again next day and the required result obtained in three of them. Five cases failed to respond, and every one of these had on admission the power to move the legs in bed combined with inability to walk or stand. These were referred to a psychotherapist. In all the recoveries an eventual sorting out of some of the mental conflicts was obtained without much trouble. The patient was told his memory for walking had now returned and had formerly been lost because of some worry, trouble, anxiety, or some situation of either real or imagined difficulty. The enormous confidence obtained from the removal of the symptoms seemed to help the patient to overcome any diffidence in his relations with the physician and to unburden himself of his deepest troubles. It was less easy to find a reasonable solution of his difficulties, although often it was sufficient to make a few suggestions and tell the patient he must choose the eventual path himself.

Follow-up.—Fourteen cases remained well without further trouble; three became well and had relapsed twice in three years but were now well. One case recovered after two injections of thiopentone, but is now paralysed again and refuses to see a doctor professionally, although she allows herself to be wheeled up by her elder sister for follow-up purposes. Of the five failures after thiopentone, one responded to a deep psychotherapeutic regime, one became an obsessional psychotic, two remained apparently unchanged, and one was untraced, so that 18 eventually made a good recovery.

Tremor

The 10 cases of hysterical tremor were very deceptive. They all recovered with suggestion under thiopentone; four relapsed in two or three days, but recovered again on repetition of the dose. All these patients were loud in their praise of the wonderful treatment, and discussed their difficulties almost with relish.

Follow-up.—Eight out of 10 were traced. Four of these relapsed within a year, and are still trembling away without much incapacity. None is willing to see a psychiatrist. The other four are well and earning their living. This is a very poor and rather humiliating follow-up after an apparently very successful beginning, and supports the psychiatric axiom, "Be wary of praise from a hysteric."

Vomiting

Six cases of hysterical vomiting, three of them in nurses, were encountered. The treatment of these was indirect suggestion—ignoring the seriousness of the symptom, giving no special diet except a full normal one, and assuring the patient that starvation would not occur. Questions about the patient's progress or the occurrence of vomiting were avoided, and a general "playing down" of the whole affair seemed to start the improvement. Five of these cases had lost their vomiting in a month and appeared well on discharge. The sixth patient continues to have the symptom intermittently and discharged herself from hospital.

Follow-up.—Three cases remained quite well, one developed an obsessional neurosis and remained a burden to her family in spite of analytical psychotherapy, and one was untraced. The sixth case was run to earth in a children's day nursery; she had apparently been to no fewer than seven hospitals with nearly every hysterical symptom imaginable. Her most recent experience had been a hysterical retention of urine treated by suprapubic cystotomy, of which she was very proud.

Discussion

The prognosis of neurosis is said to depend on the age, personality, and intelligence of the patient and on the duration, nature, and severity of the disorder. Certain of these factors are constant in this report: the age group was that of the young adult; the intelligence of each patient seemed not greatly above or below the average; and the nature and duration of the disorder were those of acute conversion hysteria. The variants are the personality of the patient and the severity of the disorder. This report is lacking in any adequate personality investigation, as if this is to be of value it must be done by a psychiatrist; the severity of the disorder is the only explored and known variant.

In a general study of recent hysterical states Kenned (1940) says that it is impossible to form an opinion about the future on the basis of symptomatology alone. Fortunately he also says: "Though often misleading until all the causative factors are known, the nature of the actual symptoms, apart from their general type, is of great prognostic value."

This tendency, in an estimation of the prognosis of hysteria, to discount the symptom and pay much greater attention to the previous personality and behaviour of the patient is supported by current psychiatric opinion, which rightly holds that the removal of the symptom cannot possibly affect the underlying personality that produced it. In fact, many psychiatrists condemn the formal removal of the disability, claiming that good psychotherapy will allow the patient to cast off his symptom without any direct reference to it.

The wider view of prognosis in conversion hysteria has been studied in military psychiatry both here and in America. Miller (1940) states that of all the severe neuroses conversion hysteria showed the highest percentage of men returning to duty rapidly, but assessment of relapse was impossible owing to difficulties of follow-up. A comprehensive survey of readjustment to civilian life was made in America in 1919 and 1924 on 830 cases of "war neurosis" (Medical Department of the U.S. Army, 1929) and in the 1919 survey the majority of hysterics were having difficulty in readjustment and little more than half were able to earn their own living. In 1924 this group showed a higher proportion of readaptation, 75% being at work.

A comprehensive survey of prognosis was made by Ros (1936), who analysed the results of the Cassel Hospital patients admitted from 1921 to 1933. Taking all the psychoneuroses, he finds that after one year 45% are well, after three years 40%, and after five years 34%. Unfortunately 60% were untraced in this sixth year follow-up, so that his recovery figures may be too low. Analysing cases of

hysteria alone, he found that at the end of four years out of 89 cases 43 were well, 23 improved, and 23 unchanged. No analysis according to symptomatology was made.

Luff and Garrod (1935) analysed the results in 500 cases of psychoneurosis treated at the Tavistock Clinic between 1928 and 1931. There were 75 cases of hysteria, and on discharge 13 were "much improved," 25 "improved," 17 "slightly improved," and 20 "not improved." After three years the figures read in the same order 17, 21, 6, and 16, the remaining 15 having relapsed. The "much improved" and "improved" groups are taken together to give a "relieved" figure of 50.6%, which after three years is the same as on discharge; these people were at work, and the "much improved" group would here be labelled "well."

This present report shows a higher symptomatic recovery rate than that obtained by other authorities, as 83% of patients were still at work for four to six years after discharge. This result has occurred in spite of inadequate psychotherapy, and the factors determining this outcome must be considered.

The selection of patients with a florid, clear-cut symptomatology and the comparative absence of cases of chronic hysteria in this series have probably improved the prognosis as a whole. Patients may also have come somewhat earlier and been more co-operative initially at a general as opposed to a psychiatric hospital, and the importance of an unusual precipitating factor such as aerial bombardment may not have been sufficiently stressed. These four considerations taken together form quite a weighty bias towards natural recovery. Moreover, although it is not always possible to know what standards are used by others in judging recovery or improvement in psychoneurotic patients the recovery or otherwise from a disabling symptom is easy to judge. Perhaps not even one out of the 66% who are here labelled well four to six years after treatment might be thought recovered at all in the psychiatric sense, although he or she is back at work, symptom-free and feeling well. Therefore this investigation of the prognosis of certain hysterical symptoms is not comparable with the results of others who have given statistics regarding the prognosis of psychoneurosis in general or in particular.

Relation of Particular Symptoms to Their Prognosis

Owing to the small number of cases and the numerical variation of each particular symptom only a suggestion of certain trends in prognosis is justified, and no one symptom can be labelled malignant or benign. Aphonia and amnesia seem to have an excellent immediate outcome—probably whatever treatment they receive within reason—and the result seems to be maintained in the follow-up. Paralysis showed a slightly less favourable result, but 18 out of 23 were well five years after leaving hospital, although these were not quite the same 18 that recovered immediately, as one of these relapsed and one of the early failures recovered after expert psychotherapeutic treatment elsewhere.

Tremor was the one symptom that supported the psychiatric theory that removal of a hysterical symptom is quite unrelated to improvement of the psychoneurotic illness itself. The immediate recovery of all 10 cases and the follow-up finding of only four well out of 10 speaks for itself.

Fits appear to be a more difficult immediate problem, as only two out of six recovered in hospital; these remained well.

Vomiting was more hopeful at first, five out of six stopping this symptom in hospital; only three of these were well five years later.

Blindness was found in only three cases, and these seem to have made an excellent recovery.

Conclusion

There is very little to add on recapitulation. The word "recovery" will never mean the same to a psychiatrist as to a physician, and one can only try to correlate physical and psychological terms. It would seem that an acute hysterical episode has not the rather grave prognosis that it is usually stated to have, and that it does not always need skilled psychotherapy or psycho-analysis to produce an apparent recovery. It is tempting to think of the hysterical personality in degrees of instability with differing thresholds of resistance, some people needing a more powerful stimulus than others to produce the reaction—rather like cerebral dysrhythmia and epilepsy in which the concept of differing grades of liability to produce clinical epilepsy is accepted. Perhaps the most stable of us would under sufficient stimulus produce a hysterical symptom in the same way that we would produce an epileptic fit if sufficient strength of electric current were passed through our brain. If so, there is at least the suggestion that in some cases of hysteria it is unnecessary to do more than relieve the symptom and discuss the patient's problem with sympathy, interest, and common sense.

Summary

One hundred cases of acute hysteria are analysed symptomatically, and the results of treatment by suggestion are recorded.

A follow-up four to six years later was successful in 90 of these cases, and the results of this are tabulated and discussed.

The suggestion is made that the outcome of such cases is better than is generally believed even although long, skilled, formal psychotherapy is not available.

NUTRITIONAL MACROCYTIC ANAEMIA IN TEMPERATE ZONES

BY

J. RUBIE, M.D., M.R.C.P.

AND

C. D. CALNAN, M.A., M.B., B.Chir.

The nutritional anaemias may be divided into primary types, in which the dietary deficiency has been the main cause of the anaemia, and the secondary types, in which utilization by the body of a complete diet is defective, usually because of some organic disorder. Occasionally the anaemia may be due to combined causes.

Macrocytic anaemia resulting from nutritional deficiency is commonest in India, Malaya, and China; it also occurs frequently in Macedonia, where it presents some different features from the "tropical" variety. A nutritional macrocytic anaemia may, however, occur in temperate zones. Such a case occurring in England is here recorded.

Similar cases have been described in England, U.S.A., Canada, Holland, and Denmark (O'Hara and Grewal, 1927; Aykroyd, 1930; Kern, 1931; Ungley, 1933, 1938; Groen and Snapper, 1937; Alsted, 1939; Townsend and Begor, 1942; Watson and Castle, 1946). Most of the authors remark on the deficiency of protein in their patients' dietary. Evidence of the relation of animal protein to tropical nutritional macrocytic anaemia was provided by

Taylor and Chhuttani (1945) in a survey of anaemia in Indians.

Of the two cases in England reported by Ungley the first showed a slow and submaximal response to "marmite," while the second was successfully treated with "campolon" liver injections.

Case Report

A widow aged 56 had been employed as a factory hand, but had not worked for the eighteen months previous to admission to hospital on May 14, 1947. She came with a letter from her doctor, which stated: "She was investigated at another hospital a year ago with the ultimate diagnosis of pernicious anaemia, but refused treatment at the time and now turns up looking like death, as you can see. She has no one to look after her." A letter from another hospital in London stated that she had attended as an out-patient on May 7, 1946, and a blood examination then showed: red cells, 3,000,000; haemoglobin, 65%; colour index, 1.08; white cells, 6,210 (P. 54%, L. 42%, E. 2%, M. 2%).

On examination it was at once noticed that she was mentally subnormal, and no reliable history could be obtained. She was quite uncooperative, refused all food on the day of admission, and was very noisy during the first night in hospital. Her appearance was one of gross physical neglect; pediculi were present on the scalp and body, and numerous scratch marks and abrasions were found. There was no abnormal pigmentation of the back of the hands or of the face. She was of small stature and of thin, spare build. The mucous membranes were pale; there was no icteric tinge. The tongue was smooth and glazed and looked sore. The parotid and submaxillary salivary glands showed bilateral diffuse enlargement. There was no lymphadenopathy. The nails were normal. Pitting oedema of the legs was present. The chest showed signs of bronchitis, and the heart sounds were faint. The B.P. was 105/65. Examination of the abdomen revealed no ascites, and the spleen was not palpable. Her speech was slow.

She complained of numbness of the legs, but, so far as her mental state would allow, no sensory loss was found to pin-prick or light touch. There was no muscular weakness or dystonia. The abdominal reflexes were absent; the biceps-jerks were present on each side, the triceps-jerks, supinator-jerks, knee-jerks, and ankle-jerks were absent on both sides. There was no plantar response.

The social history was difficult to elicit, but the salient features were: her second husband had died about eighteen months previously, since when she had lived alone in one room. Her sole source of income was from the periodic sale of personal valuables. According to a friend who lived near by, her room was in gross disorder and her culinary arrangements were chaotic. Her meals were irregular in quantity and quality, and appeared to consist mostly of tea, bread, buns, etc. Exact details of diet were not obtainable. She had been in a mental hospital on two occasions during the 1939-45 war. There was evidence that her father, stepbrother, and daughter had also been in mental hospitals.

She was interviewed by a psychiatrist on Aug. 1, 1947, who reported: "She is in a state of mild mania. She admits having been a patient in Hanwell Mental Hospital twice. She has persecutory ideas about her late husband, whom she accused of putting her away. When her medical condition allows she should be transferred to an observation ward."

Laboratory Investigations.—A radiograph of the chest revealed signs of bronchitis. A blood count showed: red cells, 1,150,000; haemoglobin, 27%; colour index, 1.16; white cells, 4,900 (P. 51%, L. 45%, E. 2%, M. 2%). A film showed anisocytosis and poikilocytosis; P.C.V. 15%, M.C.V. 130 c. μ , M.C.H.C. 25; reticulocytes, less than 1%. Stools contained no ova, cysts, or pathogenic organisms. Sternal-marrow examination resulted as follows:

Report on Myelograms.—Before folic acid: Megaloblastic erythropoiesis. On ninth day of treatment: Considerable reversion to normoblastic erythropoiesis. Urine showed a faint trace of protein and a few leucocytes; it was sterile on culture. W.R. and Kahn negative. A fractional test meal showed free hydrochloric acid after histamine up to a concentration of 38 ml. of N 10 HCl after 1½ hours.

Myelograms

	Percentage of Nucleated Cells	
	Before Folic Acid	9th Day of Treatment
Polymorph. neutrophils	14.8	40.0
" eosinophils	0.8	3.0
Metamyelocytes	8.8	14.0
Giant metamyelocytes	11.8	0.7
Myelocytes: neutrophil	15.0	3.0
" eosinophil	1.2	—
Lymphocytes	7.4	3.5
Plasma cells	0.6	—
Late normoblasts	4.8	22.0
Intermediate normoblasts	1.2	8.2
Early	0.2	0.6
Late megaloblasts	10.6	5.0
Intermediate	18.2	—
Early	4.6	—
Total nucleated cells	126,000	—
Myeloid series/nucleated R.B.C.	1.3/1	1.7/1

Treatment.—"Anahaemin," 2 ml. daily intramuscularly, was started on May 23, and two "fersolate" tablets, two vitamin B tablets, and 50 mg. of ascorbic acid were given three times a day. On May 27 and 30 and June 2 the reticulocytes were less than 1% and anahaemin was replaced by "plexan" crude liver extract 4 ml. daily. On June 6 the red cells numbered 780,000, with less than 0.5% reticulocytes. In view of this fall it was decided not to continue with plexan, and folic acid, 20 mg. daily, was started on June 9. Next day her blood count showed 1,090,000 red cells and less than 1% reticulocytes.

Progress.—Following this treatment there was a rapid rise in the reticulocyte and red cell counts, as shown in the accompanying Graph. On July 12 there were 1,260,000 red cells; reticulocytes, 6%; nucleated red cells, 124 per 100 white cells. The stained film showed anisocytosis, poikilocytosis, and polychromasia. Clinical improvement proceeded rapidly with the haematological response to folic acid. The blood pressure rose to 120/70 and all reflexes were present, though sluggish, after 10 days' treatment. The patient soon began to eat voraciously and her skin lesions healed, but her mental state remained essentially unchanged, and it was eventually found necessary to transfer her to a mental observation ward.

Comment on the Case

Davies (1945) and Holmes (1945) have drawn attention to the incidence of oedema in anaemia, due to hypoproteinaemia, especially during the stage of recovery, when much protein is being used to form haemoglobin.

The presence of pitting oedema of both legs without ascites in this patient on admission to hospital was an expected accompaniment of the severe anaemia, low blood pressure, and poor nutritional state. However, it did not improve commensurately with the clinical and haematological improvement, and when it did subside it reappeared on two occasions. No adequate explanation could be found on the last occasion of its appearance, 67 days after the beginning of treatment and when the red cell count was rising: estimation of plasma proteins showed normal values. The patient was eating a full normal protein diet. No conclusion could be drawn about the relation between the oedema and the rate of haemoglobin formation. Unfortunately the relationship of hypoproteinaemia to recovery from anaemia was not realized at the time, and earlier plasma protein estimation was not carried out.

In Groen and Snapper's two cases oedema is not reported, and the plasma proteins were normal in one of them. In the cases described by Alsted, by Townsend and Begor, and by others, oedema and plasma protein values are not recorded.

Discussion

The special interest of this case lies in the failure to respond to large doses of active liver extract, both crude

and of the Dakin and West type, and, in contrast, the immediate response to folic acid. This feature distinguishes the case from the previously reported cases of nutritional megalocytic anaemia occurring in temperate zones.

The rapid response to folic acid has been stressed recently by Kemp (1947), and the maximal reticulocyte response of 28% on the fifth day is in agreement with his findings.

It is debatable whether or not our patient would have responded to anahaemin or plexan if these drugs had been continued for longer periods. In Kemp's cases, though the response to "hepatex" was slower than to folic acid, all had shown some improvement within 18 days, whereas in our case after intense therapy not only was there shown a reticulocyte count of less than 1% but the red cell count was falling and giving rise to serious anxiety.

Oral preparations of proteolysed liver were not tried, and hence it is hypothetical whether response would have been obtained. Watson and Castle (1946) recorded a case in Boston, U.S.A., of nutritional macrocytic anaemia in a woman aged 76 who responded to intravenous injections of 20 ml. daily of the supernatant from the suspension solution of liver extract (Lilly) after failure with the usual liver extract, and also *Lactobacillus casei* factor, but the amount of the latter was only 1.3 mg. daily. Davis and Davidson (1944) have successfully treated several cases of otherwise refractory macrocytic anaemia, but none of them showed such a prominent nutritional aetiological basis as in our case.

The precise role of folic acid cannot be stated with certainty, and the mechanism of liberation from its conjugate by a liberating factor, as postulated by Davidson and Girdwood (1947), has not been widely accepted. Our patient was apparently deficient in folic acid but not in Castle's haemopoietic factor.

Summary

Nutritional macrocytic anaemia may occur, though rarely, in temperate climates, and is associated with a deficiency of protein. Previously recorded cases are reviewed and a new case is reported.

There was an immediate response to folic acid after the failure of intensive liver therapy.

We wish to thank Dr. C. D. Coyle, medical superintendent of the Archway Group of Hospitals (Highgate Hospital), and Dr. A. L. Jacobs, the chief physician, for permission to publish this case; and Dr. J. M. Alston and his staff of the Archway Group Laboratory for the pathological investigations.

Workers at the National Institute for Research in Dairying and at the Courtauld Institute of Biochemistry have investigated the widely recognized fact that cows, on "going out to grass" in the spring, often give an increase in milk greater than the amount ascribable to the extra nutrients ingested. From their preliminary results, which were published in *Nature* (1948, **162**, 845), they concluded that the galactopoietic effects of spring grass in lactating cows may be due to the presence in the grass of oestrogen.

STREPTOMYCIN IN FINGER INFECTIONS

BY

J. BRADLEY WATSON, M.B., B.S.

E. R. GRIFFITHS, M.B., B.S.

AND

L. W. PLEWES, M.A., M.D., F.R.C.S.

(From the Hand Infection Unit, Luton and Dunstable Hospital)

The use of penicillin in infections of the hand has been shown to reduce sepsis, pain, and time of healing (Florey and Williams, 1944; Grossmark and Plewes, 1945).

Streptomycin is as yet little known as a local therapeutic agent, and we have attempted to compare the results of treatment with this newer agent with those of penicillin. Two types of infection—pulp whitlows and paronychias—are used for comparison because these infections were more true to type than others and because the more serious types, such as deep palm infections, were admitted to hospital and given systemic penicillin. No case which required systemic chemotherapy of any kind has been included.

Principles of Technique.—All cases presented were incised by standard procedures under general anaesthesia and with the use of a tourniquet. Streptomycin (5,000 µg. per g.) or penicillin (1,000 units per g.) was applied as a cream. This was smeared on a vaselined gauze wick which remained *in situ* for two days. Dressings were carried out in a special "perspex" dressing-box under continuous ultra-violet irradiation—all the dressings of each day being done by the same dresser with "no touch" technique. They were changed at intervals of two days, the discharge being cultured each time. Streptomycin or penicillin was applied until culture revealed "no growth."

Bacteriology

The frequency with which various organisms are isolated from a wound depends to some extent on the bacteriological technique employed (Williams and Miles, 1945). In our cases it consisted in swabbing the affected site and seeding on blood-agar plates; these were incubated aerobically and examined the following day. A very small quantity of the cream used in treatment was included on the plate in the penicillin series, and a hole containing streptomycin, 500 µg. per ml., in the streptomycin series; in practice this gave a good indication of the sensitivity of the organism grown.

The term "coliform organism" is used to include all Gram-negative bacilli having the cultural appearances of *Bacterium coli*, *Pseudomonas pyocyanea*, or *Proteus*; the streptococci isolated were all reported as "haemolytic streptococci," but grouping was not carried out as a rule; a coagulase test was done on all the staphylococci isolated, and was positive in all cases on first culture (coagulase-

TABLE I

Coliform	12	—	—	—

negative staphylococci and atypical Gram-positive cocci were isolated from a few cases later during treatment, but are not included in the tables).

Primary infection refers to the organism isolated on first culture; secondary infection to those isolated from a second or later sample, if different from the first.

The striking fall in incidence of secondary coliform infection following the use of streptomycin is shown in two unselected series of 500 consecutive swabs received from the hand-dressing unit (Table II); one was taken during the penicillin period and one during the streptomycin period.

TABLE II

	No. of Swabs	Coliform Organism Isolated	% Coliform Infection
Penicillin period ..	500	193	38.6
Streptomycin period ..	500	37	7.4

Observations

In Table III the results of treatment and secondary infection rate are tabulated. The secondary infection rate is greatly reduced in the streptomycin group, and the number of days to "no growth" is considerably lower, while the average number of days off work is lower for the streptomycin cases.

TABLE III

	% Secondary Infection	No. of Days to "No Growth"	No. of Days off Work
Pulp Infection:			
Penicillin (60 cases) ..	20	9.0	9.4
Streptomycin (66 cases) ..	3	7.4	5.4
Paronychia:			
Penicillin (49 cases) ..	22	6.7	5.2
Streptomycin (74 cases) ..	2.7	4.8	2.3

Streptomycin was not used for acute suppurative tenosynovitis, because of lack of knowledge of the behaviour of this antibiotic within endothelial-lined cavities. In addition to the nine cases reported in 1945 eight cases have been treated by repeated aspiration of the tendon sheath and replacement with penicillin, with excellent results.

Conclusions

Streptomycin is a better local agent in the treatment of pulp infections and paronychias than penicillin.

Its use has resulted in a decrease in the secondary infection rate—more rapid healing with consequent decrease in the time lost from work.

The Ministry of Health states that patients attending out-patient departments are often referred back to their general practitioners for the issue of certificates of incapacity for work required by the Ministry of National Insurance. This procedure, which accords with the notes appearing on the covers of pads of certificates provided by the Ministry of National Insurance, is an unnecessary burden on both the patient and the general practitioner, and also puts the latter in a difficult position, since the hospital, not himself, is responsible for the treatment. The Minister is therefore asking management committees and boards of governors to make available certificates of incapacity in the out-patient departments and in clinics. While the first (Med. 1) and final (Med. 2B) certificates must be signed by the doctor in attendance and must show the cause of incapacity, intermediate certificates may be signed by the authorized lay officers. A special certificate will not be provided, and Forms Med. 7 and 8 can be adapted from "in-patient" to "out-patient." Although these certificates contain neither the diagnosis nor the usual certification of incapacity for work, the doctor should be satisfied that the patient is in fact incapable of work. The hospital stamp should include the words "out-patient department."

Medical Memoranda

Perforated Gastric Ulcer Associated with Subcapsular Haemorrhage of Spleen

An unusual complication of a common acute surgical condition is recorded. No report of an analogous occurrence has been traced in the literature.

CASE HISTORY

A woman of 69 was admitted to hospital on April 16, 1947. Eleven hours previously she had been awakened by the sudden onset of severe abdominal pain which continued up to the time of admission as an agonizing upper abdominal ache. No vomiting had occurred, her bowels had opened the previous evening, and there was no disturbance of micturition. For forty years she had suffered from intermittent attacks of "indigestion" in the form of upper abdominal pain coming on two hours after food and relieved by alkalis and dieting. She had had no recent abdominal injury.

She was a fragile, anaemic-looking woman in obvious distress. Her temperature was 98° F. (36.7° C.), pulse 82, and respirations 28. The abdomen was rigid, moderately distended, and generally tender. Liver dullness was diminished; the epigastrium was the most painful area; and there was no radiation of pain to the shoulders or elsewhere. A diagnosis of perforated peptic ulcer was made.

At operation gas and yellowish effusion escaped through a midline epigastric incision. On the anterior surface of the stomach, midway between the lesser and the greater curvatures and one inch below the oesophageal level, was a large ulcer, which had perforated. The spleen was found to be friable and surrounded by blood and clot. The perforation was repaired with interrupted Lembert sutures and an omental patch. A transverse incision was made into the left rectus abdominis. The anterior splenic surface was friable and presented a raw appearance, as if the capsule had been destroyed, and it was bleeding profusely. The splenic pedicle felt normal and there was no thrombosis of its vessels. Splenectomy was performed, and after draining the splenic bed through a counter-incision in the flank the abdomen was closed in layers.

Continuous gastric suction and intravenous fluids were instituted post-operatively for thirty-six hours. She thereafter had a smooth convalescence. Three months later she wrote to say that she was well and free from "indigestion."

The spleen measured 10 × 6 × 2.5 cm. There was no macroscopic evidence of infarction. There was a diffuse subcapsular haemorrhage. Microscopically, extravasation of blood was seen beneath a necrotic capsule. The splenic vessels were sclerotic.

COMMENT

It is tempting to ascribe the capsular necrosis of the spleen to peptic digestion. But Price and Lee (1947) report that the spleen with its capsule intact is more resistant to peptic digestion than the seromuscular coat of the stomach, intestine, or gall-bladder. Accepting such experimental observations, one might postulate a subcapsular haemorrhage of the spleen before perforation of the gastric ulcer. In a frail person with some degenerative vascular changes a minor abdominal injury might well have escaped notice and caused such an "idiopathic" or "spontaneous" haemorrhage. In this connexion one of two cases of "spontaneous rupture of the apparently healthy spleen" described by Babson and Morgan (1946) is interesting. A man of 49 had a severe subcapsular haemorrhage and splenic rupture following operation for a perforated duodenal ulcer. The ulcer was sutured in the usual way, and five days later there was a sudden collapse and abdominal pain. After two days' conservative treatment the clinical signs suggested splenic rupture, and this diagnosis was confirmed at operation. A severe cough following the first

laparotomy was thought to be the traumatic factor, and the authors infer that an associated adhesive peritonitis might have been an additional aetiological factor in causing the haemorrhage. This patient, too, made a good recovery.

Whatever the cause of the haemorrhage in the present case it is quite certain that the acute perforation masked the accompanying condition. This coincidence emphasizes one of the dangers of the adoption of conservative treatment for perforated peptic ulcer—laparotomy alone can clinch the diagnosis and exclude other possibilities.

Abacterial Pyuria Producing Bilateral Ureteric Stenosis

Abacterial pyuria is well recognized as a clinical entity of unknown aetiology which should respond dramatically to injections of N.A.B. The usual clinical picture is one of painful micturition with pyuria and haematuria in a young adult male with no pyrexia. Cystoscopy reveals an angry red mucosa which is irritable and painful. The case here recorded satisfied these essential details but presented some peculiarities over a prolonged course of three years.

CASE REPORT

The patient first came under observation in May, 1945, for an attack of fever. She was then 16 and in good health otherwise, though she had had some frequency of micturition for a few weeks. The pyrexia ($100-103^{\circ}\text{F.}$: $37.8-39.4^{\circ}\text{C.}$) lasted for two to three weeks. The white cell count was normal and the Widal reaction negative. The urine showed traces of albumin and a frank thick pyuria with haematuria microscopically. No organisms could be detected on repeated culture. Efforts were made to demonstrate acid-fast bacilli, but failed. Guinea-pig inoculation on two occasions proved negative for Koch's infection. Investigation of the kidney and bladder by descending pyelography showed no abnormality.

She was given large doses of alkalis with sulphadiazine, and the pyuria was slowly reduced. Later therapeutic trials over the next three years revealed that alkalis alone had this effect. At this stage the urea concentration was over 3%, and the urea clearance was 80% of normal, with a blood urea of 21 mg. per 100 ml.

For the next two years the patient had occasional pyrexia with headache. The pyuria persisted with varying intensity. Cystoscopy in July, 1945, and September, 1946, showed intense cystitis with a few small vesicles in the region of trigone. At different times she was given N.A.B., mandelic acid, penicillin, pyridium, sulpha drugs, large doses of alkalis, and bladder lavage. She responded dramatically every time to N.A.B.: the thick pyuria was always reduced almost to insignificance but was never completely cured. She was given 0.3 g. of N.A.B. three times, twelve times, ten times, and twelve times in four different courses. There was no response to any other drug apart from the very slow response to alkalis.

Then after 2½ years of illness she felt pain in her right lumbar region, which persisted for a few months to be followed by pain in the left lumbar region radiating to the left thigh. Descending pyelography at this stage showed a complete absence of renal function on the right side with early hydronephrosis on the left and dilatation of the lower end of the left ureter. In January, 1948, suddenly and in two to three days all her symptoms of pain, frequency, local irritation, and the slight pyrexia with headache disappeared. At the same time the urine rapidly cleared up within a week, no treatment being given to her during this period. Descending pyelography was repeated (February, 1948) and showed still more advanced hydronephrosis on the left side with delayed excretion after

45 minutes, and there was also a kink in the left ureter. The urea concentration was 1.5%, urea clearance 23% of normal, and the blood urea 45 mg. per 100 ml.

The patient was then subjected to a left nephrostomy. The left kidney appeared normal, and the slightly dilated pelvis was drained through an indwelling catheter for six weeks. This allowed renal function to recover till the urea concentration was 2%. A radiograph taken after injecting sodium iodide through the nephrostomy tube showed the dilated lower end of the ureter with an obstruction at its opening in the bladder (see Fig.). After suprapubic cystostomy the stricture in the intravesical part of the left ureter was widely opened; the end of the right ureter was found to be entirely fibrosed and closed. Descending pyelography in August, 1948, three months after the second operation, showed a normal left urinary tract; the blood urea was then 30 mg. per 100 ml. with urea clearance 50% of normal.

(April, 1948) Sodium iodide injected through the nephrostomy tube (N). The dilated lower end of the left ureter is seen with stricture (S)

COMMENT

This case presented all the essential clinical features of abacterial pyuria: painful micturition, frank pyuria with haematuria microscopically, typical appearance on cystoscopy, excellent general health with no loss of weight, and a dramatic response to N.A.B. No organisms could be detected, guinea-pig inoculation was thrice negative, and at nephrostomy the kidney showed no abnormality. Additional features in this case which do not conform to the classical description were that the patient was a female; the protracted course was for over three years; the fact that complete cure was not achieved by N.A.B.; the slight pyrexia; and the ultimate development of bilateral ureteric stricture leading to destruction of the right kidney and commencing hydronephrosis on the left. The trigone of the bladder was intensely inflamed, and it is likely that the prolonged course of this inflammation led to fibrosis with stricture of both ureteric orifices.

I am grateful to Professors S. N. Mathur and K. S. Nigam for the surgical treatment of the case.

N. N. GUPTA, M.D.,

Physician, King George's Medical College, Lucknow, India.

The Housing Progress Summary presented to Parliament as a White Paper by the Minister of Health and the Secretary of State for Scotland shows that the number of permanent houses completed in Great Britain during April was 15,110, compared with 20,160 in March. This brings the number of permanent houses completed during the first four months of the year to 67,822, made up as follows: January, 15,897; February, 16,655; March, 20,160; April, 15,110. During April homes were provided by new building, repair of uninhabitable houses, conversion, and requisitioning for 16,587 families, compared with 21,626 in March. This brings the total number of families rehoused by these methods under the post-war programme to 938,644. Apart from requisitioned houses, the number of additional homes provided is 969,289.

Reviews

TRAITÉ DE MÉDECINE

Traité de Médecine. Volume VII. Maladies du Tube Digestif et de ses Annexes. (Pp. 1,063; illustrated. 2,300 francs.) Volume VIII. Maladies du Foie et du Pancréas. (Pp. 1,166; illustrated. 2,500 francs.) Volume XI. Maladies des Vaisseaux. (Pp. 545; illustrated. 1,400 francs.) Volume XIII. Maladies des Glandes Endocrines. (Pp. 1,119; illustrated. 2,600 francs.) Published under the direction of A. Lemierre and others. Paris: Masson et Cie. 1948.

The massive *Traité de Médecine* published by Masson moves slowly towards completion. The present volumes deal with diseases of the alimentary canal (VII), the liver and pancreas (VIII), the vessels (XI), and the endocrine glands (XIII).

It is a justifiable comment, intended in no way to be critical, that French medicine, like French culture in general, has always been self-sufficient. Much of the interest this work has for the British reader is derived from this fact. Here is a system of medicine which presents in singularly pure form French modes of thought and French practice, largely unadulterated by the influence of foreign notions. This is less true of some sections than of others, but it is well shown by a study of the authorities cited. A random selection of 400 consecutive references in Volume VIII shows that of the publications quoted 346 are French, 20 American, 14 German, 6 Swiss, 3 Scandinavian, and none British. In consequence the articles frequently reveal points of view at variance with opinion in this country and sometimes have a flavour which can only be described as outmoded.

Volume VII considers in great detail the disorders of the alimentary tract. Clinical descriptions, as is usual in French works, are of unsurpassable quality. But by one author the surgical treatment of carcinoma of the oesophagus is dismissed as "opération très meurtrière," though it is fully discussed in another section. The treatment of oesophageal peptic ulcer is granted but two or three lines, and only three pages are devoted to gastroscopy. Few physicians in this country would agree that an average of 200-300 ml. of blood is an adequate volume for transfusion in severe haematemesis. Nor would all endorse the opinion that peptic ulcer is an "ambulatory affection" not requiring a special dietetic régime.

In Volume VIII the more recent tests of liver function are given scant reference—the Takata-Ara test is mentioned, but there is no word of the thymol turbidity or the colloidal gold tests. The treatment of liver aspiration biopsy is cursory. Homologous serum jaundice is omitted, and there is no discussion of the dietetic factors in cirrhosis. The views expressed on "splenogenic cirrhosis," or Banti's syndrome, have been discarded in most other countries.

Volume XI, in discussing diseases of the vessels, follows more international lines. The description of hypertension is excellent and the author's judicial attitude to the value of sympathectomy most welcome. No mention is made of clearance tests in assessing renal function. In this disorder, as in others, no appreciation of the psychosomatic aspects of disease is evident. The article on idiopathic hypotension suggests, in fact, that the importance of physiological factors in bodily disease has gained little acceptance by the general physician in France.

The descriptions of the various syndromes due to disease of the endocrine glands follow the conventional pattern in Volume XIII. The reader will be interested to learn that thiouracil and the related drugs were discovered simultaneously in France and the United States, but puzzled when this therapeutic advance is dismissed briefly as "worthy of interest." Anorexia nervosa, as so often in Continental writings, is considered as a form of pituitary cachexia. Numerous syndromes are described which have not gained general recognition in this country: of these the most appealing is seasonal hyperorchidism, which is stated to claim most of its victims in the spring.

These comments are made solely to underline some of the discrepancies between English and French medical thought. The general excellence of this vast system of medicine is not in question. It is only to be expected that five years of German occupation and isolation from the main streams of medical

progress would show themselves by a turning inward of French views and a neglect of foreign opinion. For such a work to have been produced so soon after this experience says much for the resilience of French medicine, to which it forms a striking monument.

R. BODLEY SCOTT.

AVIATION MEDICINE

Médecine de l'Aviation. Bases Physiologiques et Physio-Pathologiques. By J. Malméjac. (Pp. 330; 79 illustrations. 1,200 francs.) Paris: Masson et Cie. 1948.

Aviation medicine received a great impetus in this country and the U.S.A. during the last war. Greater speeds and manoeuvrability of aircraft, rapid ascents and descents, high altitude flying, and lengthy missions have all subjected aircrews to great stress and strain. Much research undertaken in both countries has resulted in means being devised not only for selecting the right type for aircrew but also for ensuring their safety and maintaining them in a state of efficiency. Professor Malméjac's book, which treats the subject from the physiological and physio-pathological point of view, is based mostly on work undertaken by himself and French co-workers in his laboratory in the Faculty of Medicine of Algiers. Its main object is to collect together the essential physiological facts, which form the basis of aviation medicine. The book aims at being a guide to the medical officer in charge of flying personnel and also of use to the doctor consulted by patients undertaking a flight for the first time. It should not fail to stimulate the biologist studying the behaviour of man under specific conditions and the aeronautical engineer planning future developments.

The important sections are those concerning altitude and its attendant physical and chemical changes. The effects of cold, the problem of anoxia, and the expansion of gases under low pressure are fully discussed. Ideas are advanced for eliminating factors calculated to be prejudicial to the human organism. A chapter is devoted to some of the clinical problems encountered, such as fatigue and air-sickness. In the last chapter the medical selection of flying personnel is discussed, with special reference to psychological reactions. Little reference is made, however, to the vast amount of work carried out in this country and the U.S.A. This is no doubt due partly to the restricted circulation of the reports issued during the war years and partly to security measures imposed on the findings contained therein, but since the termination of hostilities much of this work has been published and is available for reference purposes. This book is nevertheless a useful contribution to the subject of aviation medicine and is worthy of a place in any reference library.

E. D. DALZIEL DICKSON.

HANDBOOK OF E.N.T. DISEASE

Ear, Nose, and Throat. Symptoms, Diagnosis, Treatment. By George D. Wolf, M.D. (Pp. 523; 149 illustrations, including 25 in colour. £3.) Philadelphia and London: J. B. Lippincott Company. 1948.

This book is "intended for Students, Teachers, and Practitioners." The author considers that a large proportion of diseases can be diagnosed correctly on the basis of a careful history and interpretation of the symptoms alone. He has therefore taken a novel line, and most of the 25 chapters deal with symptoms, their causes and treatment. Of the five parts, the first deals with the nose, throat, and larynx; the second with the ear. Parts 3 and 4 are devoted to diseases not usually found in books on this specialty: part 3 concerns the salivary glands, lacrimation, and miscellaneous complaints, while part 4 is on facial plastic surgery. These subjects are included because the author considers the domain of otolaryngology has been raided by other specialists. Part 5 discusses points related to otolaryngology—barotrauma, allergy, avitaminosis, and the antibiotics.

It is assumed throughout that the student is conversant with the examination of the various parts of the upper respiratory tract. The first chapter gives an account of emergencies. It describes epistaxis and foreign bodies in the ear, oesophagus, and air passages, but omits retro-pharyngeal abscess and abscess of the nasal septum. Too much attention is given to

plugging of the naso pharynx. There is a detailed description of tracheotomy and intubation. In the section on the treatment of cocaine poisoning it is curious to be told that "windows should be opened wide" and injections of caffeine given intravenously. Following chapters give instruction on headaches, vertigo, nasal obstruction, dyspnoea, and hoarseness. Lists of causes are drawn up, but there is no distinction between acute and chronic symptoms, and the student runs the risk of choosing a rare cause instead of a common one.

Several of the author's statements call for criticism. Thus "No tonsil and adenoid operation is complete unless the removal of all lateral and other hypertrophied lymphoid tissue is effected." Again, "Bilateral abductor paralysis is a rare disease"; and no mention is made of the urgent need for tracheotomy, but it is merely stated that various operations have been devised for the relief of this condition. It is suggested that direct laryngoscopy is taking the place of indirect examination. Laryngeal paralyses are dealt with very sketchily and an unfortunate substitution of abductor for adductor may lead the student to misunderstand the diagram. In the section on the ear the author is not enthusiastic about antibiotics. H. states that their use is of definite value when administered in the early stage of the infection. He suggests "silent" in place of "masked" mastoiditis. The indications for surgery are clear, and the operation is described with pictures. Voice and tuning-fork tests for deafness are advised though he holds the audio meter has advantages when litigation is at stake.

An excellent feature is a good bibliography at the end of each chapter. It is doubtful, however, if this work would appeal to the British teacher or student.

W. M. MOLLISON

CHILD PSYCHIATRY

Psychiatry for the Paediatrician. By Hale F. Shirley, M.D. (Pp 442. \$4.50 or 25s.) New York: The Commonwealth Fund. London: Geoffrey Cumberlege (Oxford University Press) 1948.

In this book the importance of correlating mental and bodily health is once more stressed. The author points out how often those who deal with children, even if adequately trained in paediatrics and child psychiatry, "wear a paediatric hat in the paediatric department and a psychiatric hat in the child-guidance clinic." He sets out, therefore, to survey the field of child psychiatry in simple, straightforward language which no paediatrician can fail to understand if he will take the trouble to study this admirable volume. The reader's only possible complaint will be that the work is so comprehensive and so well illustrated by descriptions of cases that it has become too large, and he will have difficulty in finding time to study its 435 pages with the attention they deserve. The ten chapters comprise a study of the basic concepts in child guidance in which the development of the child's personality is discussed, a practical and sane description of habit training, and a consideration of physical, intellectual, emotional, sexual, and environmental factors from the educational standpoint. The methods of investigation, diagnosis, and treatment are then explained, with a final summing-up under the title of "Mental Health in a Changing World." There is no attempt to categorize disease entities, which is always a mistake in child psychiatry, since the various tendencies and reactions have not had time to crystallize, but the emphasis throughout is on the child's adjustment to the various circumstances to which he is exposed from both inside and outside. After all, much the same attitude is desirable in the study of paediatrics, so this book is to be thoroughly recommended to all physicians dealing with the young. The production fully maintains the high standard we have come to expect of all Commonwealth Fund publications.

R. G. GORDON

In the second edition of *Practical Public Health Problems* by Sir William Savage, B.Sc., M.D. (pp 197, 14s., London: J. and A. Churchill, 1949), the author discusses mainly those subjects of which he is an acknowledged master—namely, water and milk supplies, their supervision, and the diseases spread by them, and the hygiene of the food industry, with particular reference to canned foods. Chapters on housing and disinfection are included, and there is a new section on the investigation of enteric outbreaks. These are all matters with medical implications in which the medical officer of health has to advise and control his sanitary staff. This authoritative volume will prove of interest to both.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JUNE 18 1949

COST AND ADMINISTRATION OF N.H.S.

The main conclusion of the Select Committee examining the administration of the Health Services is that it is yet too early to judge whether or not the National Health Services as a whole are being managed economically. It considers that there is room for review of their detailed working and of the remuneration and conditions of service of those engaged in providing the Services. The Committee observes that the public should recognize that abuse of the Health Services gravely endangers their maintenance and further expansion. The Committee accepts the evidence that earnings of some dentists are excessive and criticizes those responsible for framing the original estimate for supplementary ophthalmic services, observing that the fees paid are too high. The Committee also notes that there has been abuse of the Pharmaceutical Services and remarks that to avoid this the Health Departments should make such regulations as are practicable to prevent excessive or wasteful prescriptions. It recommends that administration of hospitals should be reviewed as soon as enough working experience is available and advocates the setting up of a uniform system of costing for the hospital services in England and Wales; in particular, the question should be considered of establishing an internal audit similar to that carried out by the Scottish Regional Boards. Its summary concludes thus: "The conception of a free, comprehensive Health Service can be made to work only with the good will and co-operation of all the parties in it. All branches of the Health Service are making great efforts to work the new machine efficiently. Nevertheless there are indications of difficulty in maintaining professional standards under the Health Service and there are delays and difficulties in obtaining treatment. These difficulties can be overcome only by constant supervision and the utmost endeavour on the part of all concerned—the Department, the professions, and the general public—to use the Service wisely. Only in this way is it possible to avoid waste and to make the best use of public funds."

The cost of administration amounts to only 2% of the total National Health bill, and at present it seems that the Executive Councils suffer from a shortage of suitable staff for the job. The Committee therefore considers that administrative costs and staff seem to be on a reasonable level, but recommends a review by the Ministry of Health when the Services have settled down, basing this observation, no doubt, upon the remark made by Sir William Douglas that he hoped that "the activities of the Ministry will diminish as the organizations which have been produced get down to it and deal with the actual provision of Health Services themselves."

The introduction to the Report draws attention to the unprecedented nature of the responsibilities created by the

scheme, a scheme which has to provide various benefits to nearly 50,000,000 people and administer over £350,000,000 out of public funds. In February of this year the Dental Services in England and Wales were costing the country £900,000 a week, and if the public demand for them did not come down the estimate for a full year would be over £45,000,000. It was stated in evidence that a dentist in Renfrewshire was, towards the end of last year, receiving between £1,300 and £1,400 gross a month. For 1949-50 it is estimated that 9,000 dentists will cost the country £30,904,000, as compared with £45,800,000 paid to over 19,000 general practitioners.

The Report refers to the "conflict of opinion on the critical issue of whether or not doctors are being paid in accordance with the recommendations of the Spens Report. . . . To bring them into line with present-day values the Department have added a percentage figure which doctors claim is inadequate." It was not within the province of the Committee to comment on this matter, but it considers that there is scope for review of the remuneration and conditions of service in the family practitioner services. In reply to a question put to him at the Committee, Mr. H. H. George, Accountant-General to the Ministry of Health, said that doctors in dense urban areas were much better off under the National Health Service than they were under N.H.I., but that those in what might be called a good-class practice were getting less. In reply to the question, "Do you think doctors are doing as well as the Spens Committee anticipated they should do?" he replied, "I think so, quite clearly." When questioned on the betterment factor, Mr. George said that the 20% increase on net remuneration was prescribed by the Government on the basis apparently that this represented the average increase in professional salaries. The Report states, "that in many areas patients now have to wait in queues for examination so that treatment is delayed and that in such areas doctors are seriously overworked." Because of this the Committee recommend that everything should be done to facilitate entry into the medical profession. We recall once more the words of Mr. Messer in the House of Commons that the situation cannot remain as it is. It is admitted that general practitioners are overworked, that the cost of living for the professional classes has nearly doubled since 1939, and that the Spens recommendations should be brought into line with the post-war value of money. It is therefore pertinent to ask how Mr. George arrives at the conclusion that "doctors are doing as well as the Spens Committee anticipated they should do." Comparison with what the dentists are earning, with their limited hours of work, less arduous training, and infinitely less responsibility, must make general practitioners feel with justice that they are the Cinderellas of the National Health Service. It should be pointed out that only the medical service is a guaranteed service, the medical profession having accepted collective responsibility for all patients coming into the scheme. The dental and ophthalmic services are not guaranteed, dentists and opticians being free to attend or not to any person who applies for treatment: patients cannot be allocated to them.

Fourteen Regional Hospital Boards in England and Wales and five in Scotland act as agents for the Ministry

of Health and the Department of Health for Scotland in the general administration of hospitals. Under these Boards there are 376 Hospital Management Committees in England and Wales and 84 Boards of Management in Scotland. In England and Wales the Management Committees submit their annual estimates to the Regional Boards, who, on this basis, submit Regional estimates for final approval by the Ministry. The teaching hospitals are under their own Boards of Governors and submit their estimates direct to the Ministry. In Scotland the teaching hospitals are under the Regional Hospital Boards, which control their Boards of Management through an internal audit staff which visits them and not only examines expenditure but also deals with questions of administration and the statistics of costing. This provides an efficiency as well as a financial audit, and so it is claimed gives the Scottish Regional Boards an added sense of responsibility for controlling expenditure. The evidence of hospital administrators makes interesting reading and shows that those responsible for it, at the moment much overworked, are still not clear what would make for greater efficiency. In the view of the chairman of a Regional Hospital Board it will take years before the system will run smoothly. He considered that "so far as possible the hospitals shall be left with such measure of independence as they can be left with, and for that reason it is necessary that you do decentralize the control of them into Hospital Management Committees and in fact to House Committees of individual hospitals, so that you keep as far as you can the individuality of hospitals." Another witness stressed that the effective financial control should lie with the Hospital Management Committee, and later in the discussion the chairman of a Regional Hospital Board remarked, "I would go so far as to say that the Regional Hospital Boards are not necessary." When it came to the question of the cuts in hospital expenditure recently demanded by the Minister of Health one of the English witnesses said he could not see how it would be possible to cut expenditure without interfering with the services to patients. The Minister has now modified the original plan so that beds may remain in use and urgent development proceed. There is much yet to be learned about the most efficient way of administering and financing the hospital services, and the Select Committee would seem to have been impressed by the way they manage these things in Scotland.

The above are but some of the points brought out by the Select Committee's investigation into the administration of the National Health Services now presented in a document of unusual interest, giving as it does in the Minutes of Evidence the actual experience of those responsible for the administration of the services at various levels. Although it was not for the Committee to comment on the terms of remuneration, yet it considered that the terms and conditions of service for those providing family practitioner services should be reviewed. In the meanwhile practitioners must wait until the Ministry of Health has collected its evidence before negotiations can begin on what the report describes as the critical issue of whether or not doctors are being paid in accordance with the recommendations of the Spens Report.

INDICATIONS FOR SPLENECTOMY

The indications for removing the spleen have never been clearly defined. In the past there has been some divergence of opinion on the efficacy of splenectomy in the treatment of a number of diseases. About traumatic or spontaneous rupture of the spleen there has never been any doubt: although difficulties in diagnosis often arise from the delay in onset of symptoms or from the absence of a clear history of trauma, when the diagnosis is established splenectomy is imperative to prevent death from haemorrhage. Splenectomy is also the treatment of choice for simple or hydatid cysts of the spleen. The uncertainty of the results of splenectomy in the treatment of other diseases has arisen from a lack of precise knowledge of the causes and effects of splenomegaly, and from a tendency to group together diverse pathological conditions under comprehensive terms like Banti's disease and von Jaksch's anaemia. In a recent lecture to the Ulster Medical Society, printed in the opening pages of this issue of the *Journal*, Dr. Ronald Bodley Scott has summarized the current views on splenic function in health and disease with special emphasis on the indications for splenectomy.

In the assessment of the value of splenectomy in disease the physiological or abnormal functions of the spleen in relation to the particular disease must be considered. In progressive occlusion of the bone-marrow by sclerosis or neoplastic invasion the spleen often takes over the function of red-cell formation, and splenectomy would be disastrous, since the only efficient source of haemopoiesis would be removed. Fortunately these conditions are usually readily recognized by the appearance of immature cells in the peripheral blood, by the sparse cellularity of marrow smears, and by radiological changes in the bones; but in myelofibrosis trephine biopsy of the marrow may be necessary to confirm the diagnosis.

In familial acholuric jaundice the primary abnormality lies in the red cells, which are more spherical and more fragile than normal. The spleen destroys these fragile spherocytes in large numbers, and splenectomy is a palliative, but uniformly successful, form of treatment in that it removes the main organ of red-cell destruction. Splenectomy also reduces the degree of spherocytosis, since red cells normally increase in thickness in passing through the spleen. The operation is not always so successful in Cooley's anaemia, and in sickle-cell anaemia, where the abnormality is also in the erythron, splenectomy is for reasons unknown quite ineffective. Acquired haemolytic icterus differs from the familial variety in that a circulating haemolysin causes the abnormal fragility and shape of the red cells.¹ It is not surprising that splenectomy has a varying amount of success in this disease, and the operation is indicated only in those patients whose anaemia persists or progresses in spite of repeated blood transfusion. It is important to bear in mind that excessive red-cell destruction may take place in a spleen which is enlarged from other disease. If the haemolytic anaemia is such

cases is severe and the primary disorder chronic, splenectomy will help the patient, and Bodley Scott cites a patient with Hodgkin's disease who was restored to good health for five years following splenectomy.

A group of disorders in which splenectomy is of value is that which has become known as primary or functional hypersplenism. Accumulating clinical evidence suggests that excessive splenic action inhibits the production of red cells, granulocytes, and platelets by the bone marrow, and that the brunt of this inhibition may fall on any one of these functions or on all three simultaneously. The suggestion that splenomegaly from any cause might inhibit granulocyte formation was probably first made by Bauer in 1899,² but the significance of splenic neutropenia was not fully appreciated until Wiseman and Doan³ described the syndrome of splenomegaly, neutropenia, and sepsis occurring, as a rule, in middle-aged women. In these cases the proportion of granulocytes in the bone marrow is high, but mature forms are scanty. The changes in the spleen are non-specific. Splenectomy often leads to a complete cure, but in Felty's syndrome, where there is an associated polyarthritis, there is seldom any improvement in the joint affection. Thrombocytopenic purpura is an analogous condition, in which splenic inhibition affects the megakaryocytes. The bone-marrow smears show an abundance of megakaryocytes, but mature platelets are absent. Splenectomy is followed by an immediate increase in the platelets, but the purpuric tendency does not always improve so rapidly. It must be remembered that thrombocytopenia may also arise from drug allergy, leukaemia, and other infiltrations of bone marrow; the criterion for splenectomy in thrombocytopenia should, therefore, be the finding of *abundant immature megakaryocytes in the marrow*. In splenic pancytopenia the associated anaemia may be haemolytic or non-haemolytic. The bone marrow is highly cellular, and splenectomy usually cures.⁴ Neutropenia, thrombocytopenia, and anaemia often occur when the spleen is enlarged in other diseases, such as leukaemia, lymphadenoma, and kala-azar. In these cases, which are sometimes referred to as secondary hypersplenism, it is probable that the spleen exerts the same inhibitory effect as in primary hypersplenism: for example, the anhaemopoietic crises of acholuric jaundice might be attributed to secondary hypersplenism.⁵ It is possible that those cases of secondary hypersplenism in which the symptoms of bone-marrow inhibition predominate will benefit from splenectomy. It is clear that in selecting patients for operation it is essential to differentiate between the symptoms of hypersplenism and those of the primary disorder.

Banti's syndrome has sometimes been regarded as a condition amenable to treatment by splenomegaly, but Howells⁶ showed that there was no increased expectancy of life after splenectomy. Views on Banti's disease have altered considerably in recent years. It is known that the majority of cases are due to hepatic cirrhosis, and others follow portal hypertension caused by other conditions. It is better to use the term "congestive splenomegaly," and to try to find the precise cause in each case. In congestive splenomegaly due to hepatic cirrhosis splenectomy is indicated only when the symptoms of hypersplenism—anaemia, leucopenia, or thrombocytopenia—predominate over those

of portal hypertension. In the relief of portal hypertension splenectomy is far inferior to operations designed to shunt venous return from the portal to the systemic channels. When congestive splenomegaly arises from thrombosis of the splenic vein it is cured by removal of the spleen, a fact which might well account for some of the earlier enthusiastic reports on the value of splenectomy in Banti's disease. The indications for splenectomy are becoming clearer and the need for judicious selection of cases is apparent. Each case must be considered individually and the function of the spleen carefully assessed in relation to the patient's disease.

THE SORE TONGUE

Soreness of the tongue is a symptom shared by a number of diseases patently due to, or accompanied by, nutritional defects. It is common in sprue and other forms of steatorrhoea, in pellagra, in Addisonian pernicious anaemia, in chronic hypochromic anaemia, in cirrhosis of the liver, and after the administration of folic acid antagonists. Although a sore tongue and a suspected or proved deficiency of one of the B group of vitamins links these disorders, the pattern of ectodermal change varies in the different diseases, and only glossitis is common to all. A careful anatomical study would be valuable, for it is important to know whether the changes are similar in all these varieties of glossitis. A few examples will show the varied pictures encountered: in steatorrhoea, stomatitis accompanies glossitis, though this is rare in pernicious anaemia; in the latter and in hypochromic anaemia there is often prematurely white hair, but the second of these is associated with angular stomatitis and with changes in the nails and hypopharyngeal mucosa which are not observed in the first. Again, deficiency of riboflavin is recognized as the cause of a syndrome in which angular stomatitis, corneal vascularization, and a scaly desquamation in the naso-labial folds and the perineum are combined with a sore, "magenta-coloured" tongue. Stomatitis and glossitis are also familiar signs in nicotinic acid deficiency.

The relation between these various syndromes is unsettled, but two recent papers by Dr. Alexander Brown, one of which was published in the *Journal* of April 23 (p. 704) and the other which appears in this issue, contribute to our understanding of the problem, while underlining its complexity. He has observed seven patients with Addisonian pernicious anaemia in whom sore tongue was a feature. In four of these glossitis made its appearance while the anaemia was effectively controlled by liver extract—an observation proving that sore tongue is not necessarily related to deficiency of the anti-pernicious-anaemia principle of liver. Calcium pantothenate cured the glossitis in these patients; in the two to whom it was administered nicotinic acid was ineffective. In one patient, receiving full doses of liver extract, stomatitis and glossitis were relieved by nicotinic acid, but when the symptoms recurred nicotinic acid was only partially effective, and the condition was cured after riboflavin was added; in a second relapse riboflavin was again curative after calcium pantothenate had proved ineffective. In one untreated case sore tongue was not relieved by calcium pantothenate, nicotinamide, or riboflavin, though folic acid and, later, liver extract were completely effective. The seventh patient, while receiving full doses of liver extract for a relapse of her anaemia, developed the typical syndrome of riboflavin deficiency; she recovered rapidly when this vitamin was administered. In his second paper Dr. Brown reports the case of a patient in whom steatorrhoea, persistent glossitis, and stomatitis followed the

operation of ileocolostomy for what was probably regional ileitis. This patient was observed over a period of two years, and it was possible to prove that on separate occasions the oral symptoms were controlled by calcium pantothenate, by inositol, by yeast extract ("marmite"), and by intramuscular injection of a refined liver extract ("anahaemin").

The significance of these observations cannot yet be fully assessed. Dr. Brown suggests that in the patient with ileocolostomy sore tongue was due to pantothenic acid deficiency; this appears to be true also of at least four of his patients with pernicious anaemia. Perhaps a metabolic system should be visualized which may break down at different levels. The anti-pernicious-anaemia principle of liver corrects the fault in most cases, but in some pantothenic acid, or the closely related inositol, is required.

PLAGUE IN CALCUTTA

A few weeks ago Professor S. C. Seal of the All-India Institute of Hygiene and Public Health warned his colleagues at the Calcutta Medical Club that the present outbreak of plague in India might assume epidemic proportions. Plague reappeared in Calcutta fourteen months ago and exactly fifty years after the beginning of the last pandemic. The disease seemed virtually to have disappeared from the city for the last twenty years. During this period imported cases were occasionally reported, but there had never been anything resembling the epidemic which began on April 17, 1898. Curiously enough, the first case of plague to be diagnosed in Calcutta in 1948 appeared on the same date, April 17, and in the same Colootola area. Later, 11 cases were shown to have occurred previously, and of these patients 8 had died. Subsequently there was a much larger incidence of milder cases.

Altogether in 1948, 276 suspected cases of plague were notified in Calcutta. Of these only 173 were clinically accepted as cases of plague, including 35 cases confirmed bacteriologically. There were 23 deaths, giving a fatality rate of 13.3%, and the peak of the outbreak was in the last week of April. About 5,000 rats were examined in April and May, 1948, and 19 showed evidence of plague infection¹; of these, 7 were *R. rattus* and 12 *R. norvegicus*. The organisms in most instances, however, were scanty, and the same feature was observed in human cases.

In 1949 the first cases began to appear towards the end of February—a little earlier than in 1948. The total number of suspected cases recorded up to May 23 was 265, of which as many as 240 cases had been accepted clinically, while in 70 or more the diagnosis of plague had been confirmed bacteriologically. Thus the number of cases has already exceeded the total for last year. Among the 265 notifications there were several septicaemic cases, and 16 were of the pneumonic type with 15 deaths. In this group of 16 only five cases were available for bacteriological examination, and in four of them *P. pestis* was identified; the last patient received streptomycin before material for examination could be collected and is the only one to have recovered. In the whole series there have been 52 deaths, the fatality rate thus being 19.6% as against 13.3% in 1948. Even if the pneumonic cases are excluded the fatality rate works out at 14.75% in spite of treatment with streptomycin and sulphonamides. Infected rats have also been more widely distributed than last year. Among 8,000 rats examined in recent months 32 were found to be infected, including 8 live rats. Already eleven wards of the city of Calcutta besides the Dum Dum and Howrah city areas are involved in the outbreak. In

contrast to the findings last year the number of organisms in the spleen and in lymph-node smears has been much larger, and in fact blood smears have also revealed *P. pestis*. Another difference noted this year is that the incidence of the disease has not yet begun to decline. In brief, over the last five months in Calcutta there has been a geographical extension of the disease to different parts of the city and suburbs, a higher incidence of cases, and greater virulence, as evidenced by the occurrence of some pneumonic and septicaemic cases and an increased fatality rate. It may be added that plague has reappeared not only in Calcutta but also in many other towns and cities of India where the disease has been either absent or quiescent for many years.

These trends provide disturbing evidence of some change which, if it continues, may set the stage for a major epidemic of plague. Calcutta had 239 deaths from plague in 1898 and 2,029 deaths in 1899. The following year there were 8,275 deaths in Calcutta and 13,285 in Bombay.² The experience of the last two years does not show the same steeply rising incidence, but it is clearly wise for the public health authorities to warn local medical practitioners, as they have done, of the possibility that plague may again become a major problem. The last few deaths from plague in Bengal and Calcutta were in 1925, and since then a new generation of doctors has grown up with few opportunities of studying the clinical effects and epidemiology of *P. pestis*. Fortunately much more is known now about prevention and treatment than was the case at the beginning of the century.

THE ELECTRONIC BRAIN

During the past two years a mechanical brain has been developed at Manchester University by Professor F. C. Williams, of the Department of Electrotechnics, to meet the requirements of two of the university mathematicians, Professor M. H. A. Newman and Mr. A. W. Turing. The machine includes 1,000 wireless valves, which are able to retain for long periods electrical charges representing numbers. It is similar to, but in some respects different from, machines in this country and the U.S.A. in employing the electronic method of storing information. This mechanism affords the machine a "memory" which lasts until it has been cleared of its charges. It can "recall" how far it has progressed in its calculation in order to supply the next step, and is able to "choose" between two alternatives at a great number of points in an extensive chain of calculations. The valves, like nerve cells, not only store the messages they receive, but can be inhibited from action, can be arranged to transmit messages in response to impulses from one or several other valves, and may be prevented from transmitting if the impulses fail to arrive.

The speed of the apparatus is several thousand times faster than that of the human brain. It can answer a simple problem under a second, and in half an hour is able to solve a calculation that would employ a mathematician for several months. It has just completed, in the space of a few weeks, a problem stated in the seventeenth century and that was in the last stages of its solution.¹

An analogy between the human brain and its present electronic equivalent was made by Professor Jefferson in his Listerian Oration. The machine's "memory" may rely on the same mechanism as that of man, but extensive damage to the human brain can occur without great loss of memory, whereas partial destruction of the machine is accompanied by a comparable loss of function. But we understand further developments of the machine may make

¹ Seal, S. C., and Lal, R. B. *Ind. med. Gaz.*, 1948, 83, 145.

² *Ibid.*, 1948 83, 137.

¹ *The Times*, June 11, 1949.

it in this respect comparable with the brain. Further, the machine answers only set problems, and its method of reply is pre-set by an intelligent staff who supply it with the appropriate questions. It cannot, of course, as Professor Jefferson points out, create its own ideas and the language to express them: it will attempt the insoluble until stopped by the operator; it has no opinions, no creative thinking, and no emotions. "We feel, perhaps," Jefferson said, "that we are being pushed, gently not roughly pushed, to accept the great likeness between the actions of electronic machines and those of the nervous system"; but he pointed out that advances had been made by observation of the living thing itself, and stressed again and again in his fascinating oration that we accept likeness to mechanism only as analogy and not as identity. The living nerve cell and the nervous impulses had no counterpart: "They are not exactly like anything except themselves." Again, speaking of the brain, he observed that "however its functions may be mimicked by machines it remains itself and is unique in nature." The emphasis on the uniqueness of the thing in nature is important, for, as Jefferson observed, the ill-informed may be tempted to go to great lengths of fantasy. It had been a hard task to dissuade man from reading into animals the qualities of the human mind; he saw the new and greater danger threatening—that of anthropomorphizing the machine.

DOCTORS TAKE THE RORSCHACH TEST

Any data bearing on temperamental fitness for a medical career will be studied with interest by those who are concerned with the selection of medical students. The Rorschach ink-blot test, which has undoubted usefulness in the assessment of some aspects of temperament, is familiar to psychiatrists as an aid to the study of personality and to differential diagnosis. But it has not, up to the present at least, found much application in the field of occupational psychology. In a recent article Schachter¹ has described the results obtained when the test was given to 20 doctors practising in Marseilles. The subjects were mostly young, and six of them were women. The aims were, first, to obtain control records from a group of highly educated normal individuals, and, secondly, to discover how a medical training might affect performance of the test. Although the study was not primarily concerned with vocational fitness, the findings may be of some interest to those who aspire to select personalities specially suited to the vicissitudes of a medical career.

The outcome of Schachter's inquiry was by no means unflattering to the medical men and women who offered themselves as subjects. According to the accepted code of Rorschach interpretation, they were found in general to possess a practical type of intelligence, a somewhat extraverted personality, and a good capacity for adaptation. It is hardly surprising that some of the ink-blots were interpreted as anatomical designs, which the author attributes, reasonably enough, to special training rather than to the rigid interests of the hypochondriacal. An interesting point was that no fewer than eight of the subjects offered occasional responses based exclusively on the colour of the designs. This is a type of response commonly encountered in the records of abnormal individuals and is conventionally held to indicate crude impulsive traits. It is possible that this interpretation will require revision in the light of Schachter's findings. On the whole, however, the patterns of response obtained were characteristic of any normal and well-educated group, and the special features noted are too slight to be of value for vocational selection. More details about the type of work done by the subjects would have

been interesting, and also about the success and satisfaction which each had attained in his professional career.

It is to be hoped that the limited character of Schachter's study will not deter other Rorschach workers from following up the topic which he has begun to explore. A large-scale Rorschach study of medical students followed up for a number of years after qualification would be of great help in assessing the prognostic value of the test. There is to-day an urgent and understandable demand for quick methods in judging personality. But it is not always realized that long and laborious research must be undertaken before any test method can be trusted to give reliable indications of temperamental fitness. There is at present no weapon in the psychologist's armoury that enables him to attack with any confidence that most difficult problem of temperamental fitness for a career in medicine.

DR. ELLIOTT P. JOSLIN

The medical profession of Britain will wish to join us in saluting Dr. Elliott P. Joslin on the occasion of his 80th birthday, which he reached on June 6. For the past 50 years Dr. Joslin has been studying the problems of diabetes and has won a world-wide reputation as an authority on this disease. In recognition of this the British Medical Association this year added his name to its distinguished list of foreign corresponding members. Diabetics all over the world owe him a great debt, for in the pre- and the post-insulin days he has been unflagging in his efforts to evolve a rational treatment of this disease. Not only that, but he has been a great educative force, and, charmingly characteristic of the man, he has conferred medals on those who have survived with their disease for varying lengths of time. At Brussels last week he presented such a medal to Dr. R. D. Lawrence, who for 29 years has led an active professional life as an expert in diabetes, and was among the first, we understand, to receive insulin in this country.

Dr. Joslin started practising medicine in Boston in 1895 and taught in the Harvard Medical School, beginning as assistant in physiological chemistry in 1898 and ending as clinical professor of medicine from 1922 to 1937. In 1943 he was presented by the American Medical Association with its Distinguished Services Medal and Award. In the words of the *New York Times*, "the thousands of patients who have passed through the Joslin Institute in Boston will join physicians in wishing Dr. Joslin more years of activity."

BIRTHDAY HONOURS

Among the Birthday Honours to medical men—a full list appears elsewhere in this issue—we note in particular the knighthood bestowed upon Mr. H. S. Souttar. Mr. Souttar for many years gave freely of his time and energy to the British Medical Association. Apart from serving on its various committees, he was from 1934 to 1937 chairman of the Representative Body and from 1939 to 1943 chairman of Council. He was chairman of the Medical Planning Commission set up by the B.M.A. early in the war, the draft interim report of which was published in 1942. He created, we believe, a record in then becoming also president of the B.M.A., in 1945. His colleagues in the Association and the profession at large will be gratified to see his many services to the medical profession thus fitly recognized. The B.M.A., too, will welcome the bestowal of the C.B.E. on Professor R. M. F. Picken, who for several years was a member of Council and chairman of the Public Health Committee, and of the O.B.E. on Dr. Noel Waterfield, who for many years has been a member of Council and is also chairman of its Ethical Committee.

¹ *Acta neurol. psychiat. belg.*, 1948, 48, 22.

MEDICAL ABSTRACTING

CONFERENCE HELD BY UNESCO

Soon after Unesco had been established as one of the specialized agencies of the United Nations its Department of Natural Sciences began to consider the problem of abstracting in medicine and biology. During the past two and a half years it has held meetings composed of representatives of non-profit-making abstracting agencies, and its activities have been jointly sponsored by the World Health Organization. The first full meeting of the Committee on Medical and Biological Abstracting and Indexing set up by Unesco met in Paris a fortnight ago under the chairmanship of Dr. Hugh Clegg, Editor, *British Medical Journal*.

The meeting was opened by the director-general, Monsieur J. TORRES BODET, who said that the word "abstract" nevertheless represented something very concrete. Behind the condensed analysis, the initials, and the abbreviations was hidden a useful effort of thought. After the second world war communications between the greater part of Europe and other continents had been cut for nearly five years; a real desire had made itself felt to know what had been done. Earlier there had been much praiseworthy initiative, and international co-operation had existed in the sphere of medicine and biology. But at the end of the war there was urgent need for an immediate and more embracing effort than there had been in the past. Unesco took this question up without delay, even when it was only a preparatory commission. Since then, for more than three years it had not ceased to encourage co-operation between the abstracting services in medicine and biology. What had already been achieved was by no means negligible, even if it only indicated the direction for future progress. First of all it was important to gather together experts on the subject from various countries; jointly they sought for a solution of common problems, and tried to resolve any conflicting interests there might be between different publications. As the committee included only non-profit-making agencies in order to make their services available at a low price, the whole scientific world became its beneficiaries. As one of the aims of the committee was to avoid duplication of effort the director-general applauded the decision of the World Health Organization not to enter the field of abstracting without prior consultation with the Committee for Co-ordination of Abstracting in the Medical and Biological Sciences. The results already obtained were only clearing the way. It was good to encourage and co-ordinate, but what was important now was to make such co-operation more effective. The committee would have an important part to play in the International Conference on Scientific Abstracting to be held by Unesco on June 20. If this conference decided to set up an international bureau for co-ordination of scientific abstracting this committee would, he hoped, be an active element in it. But in considering this they would not forget the immediate tasks of the present session, such as the decision to prepare a complete list of medico-biological journals, to standardize nomenclature and abbreviations, and to plan abstracting so that nothing would be missed from medico-biological literature. Many problems were presented by the choice of publications for abstracting, by editing, by the principles of classification, and by the gradual formation of a scientific polyglot vocabulary. It was necessary to bring to this work not only expert knowledge but the spirit of consideration and tolerance. In their field he was convinced that the committee would surmount their difficulties and thus contribute to the progress of science and international understanding.

Statements were then made by Dr. N. HOWARD JONES, director of Library and Reference Services of WHO, and by Professor F. VERZAR, on behalf of the Food and Agriculture Organization, both of them expressing the interest of their agencies in the subject and aims of the committee. The meeting was then addressed by the director of the Department of Natural Sciences, Professor P. AUGER, who observed that Unesco intended to carry on the work begun in the field of abstracting, and was conscious of the size of this task owing to the fact that some 50,000 scientific periodicals were now being published in the world. Unesco had under consideration the setting up of a small permanent body to put into effect the resolutions passed by this and other committees, and the com-

mittee he was addressing would have to consider whether it would merge itself into a larger bureau on scientific abstracting, a matter which would come up for discussion a fortnight later. One of the problems of this committee was to consider how it should co-ordinate its work with the bigger conference.

Background

Dr. CLEGG, chairman of the committee, for the benefit of those present for the first time, then gave an account of some of the work that had been done since 1946. Towards the end of the war the British Medical Association had decided to start a medical abstracting service as soon as conditions permitted, and had learned that a similar idea had occurred to a group of scientists in Amsterdam, who, under the general title of *Excerpta Medica*, intended to publish a series of abstracting journals in the English language. It was this bilateral effort and the possible duplication of time and effort that might arise from it that had determined Unesco to set up a co-ordinating committee: in this Dr. I. M. Zhukova had claimed an important part. Other groups then became interested in the project, and in particular the National Research Council in Washington had expressed its opinion that Unesco had "a unique opportunity to perform a useful function in the international aspects of science by (a) assisting biological and medical abstracting services to accomplish a full coverage in biology and medicine; (b) elimination of wasteful duplication; and (c) publication at reasonable prices." The National Research Council thought that these objectives could be reached by non-profit-making enterprises.

The Interim Committee passed a number of resolutions. One of these was to the effect that the duplication of specialist abstracting journals was undesirable, and another was that a comprehensive abstracting service in the sense of abstracting all articles of all journals was neither possible nor desirable. The abstracting services represented in the Interim Committee undertook to see how far they could collaborate by the exchange of abstracts and by avoiding duplication of abstracting sections.

There had been two opposite points of view on how best to co-ordinate the work of abstracting. One of these was that one international abstracting service for biology and medicine should be set up, and the other that existing agencies should continue in being and attempt to correlate their work. Dr. Clegg thought it would be impossible to realize the ambitious scheme of setting up one international agency, and it would be much better first to attempt to secure agreement on small details of importance to those editing, publishing, and using abstracting journals. There was, for example, the question of adopting a common method of abbreviating titles of periodicals, and the Interim Committee had passed a resolution in favour of the method used by the *World List of Scientific Periodicals*. There was at the moment no uniformity in the method of abbreviating titles. Similarly there was no uniformity in arranging the bibliographical entry to an abstract. There was also confusion in the use of symbols and abbreviations.

Dr. Clegg concluded by suggesting that at the end of its deliberations the committee might suggest that Unesco should provide instruments useful for all abstracting agencies. Those that seemed to be feasible were: (1) A polyglot glossary for the medical and biological sciences. (2) A published list of existing medico-biological journals and their abbreviations. (3) A handbook of internationally accepted abbreviations and symbols.

Towards Co-ordination

Professor M. W. WOERDEMAN, editor-in-chief of *Excerpta Medica*, in a short paper on the co-ordination of the work of abstracting services, pointed out that in medicine there were groups of readers whose requirements differed greatly, owing to increasing specialization and the consequent narrowing of interest on the part of the reader. It would not be possible to satisfy the many divergent interests by a single abstracting service. When a scientific article was of interest to more than one group of readers it might be preferable to have it abstracted by different experts, who alone would know the special interests of their particular group. Any attempt to centralize abstracting work would lead to this being overlooked. He did not think

that the overlapping of fields of interest of different abstracting organizations was necessarily a bad thing. There should be avoidance of overlapping in the preparation rather than in the publication of abstracts. For the less well-known languages the various abstracting agencies might jointly use the services of common offices in the countries of these languages. Co-ordination of work would be facilitated by joint agreement on the arrangement of the details of an abstract, nomenclature, abbreviations, classification, and indexing, and also on the instructions to be given to abstracters.

Arrangement of Abstract Entry

On one of the points referred to by Professor Woerdeman—the arrangement of bibliographical information in abstracting journals—Dr. ISABELLA LEITCH, director of the Commonwealth Bureau of Animal Nutrition, read a paper which was accompanied by a printed document showing the wide variety of usage in various abstracting journals. She considered that the bibliographical information should be set out in this order: (1) author's name; (2) the place where the work was done; (3) the full title of the paper; (4) a translation, not necessarily literal, of the title; (5) the name of the journal, year of publication, volume, part number, first and last pages of the paper.

In a discussion on this Dr. G. M. FINDLAY said the evidence presented to the Royal Society Conference on Scientific Information showed that most journals placed the title of the paper first in order. But the committee voted heavily in favour of the order suggested by Dr. Leitch, whose paper also pertinently referred to the sins of omission and commission of editors and authors, all of which had a bearing upon the problems of abstracting and indexing.

The User's Viewpoint

Mrs. EILEEN R. CUNNINGHAM, of the Medical Library Association of the U.S.A., gave a helpful analysis of the results of a questionnaire sent to medical librarians in North America and elsewhere. A very large majority of librarians were in favour of standardizing the form of bibliographical data, and advocated that the author's name should come first. They stressed the importance of promptness of publication both of abstracts and of indexes. As users they expressed a preference for the informative as against the indicative type of abstract.

The point of view of the user was also cogently expressed by Professor P. LÉPINE, a research worker in the Institut Pasteur of Paris. His paper was based on his own experience and on an inquiry made among his colleagues. Professor Lépine urged that there should be speedy publication; the users he had consulted would prefer a short abstract to be published quickly rather than a long abstract which would appear some months after the publication of the original article abstracted. From what he said it seemed clear that research workers needed a quick reference system, and one speaker suggested that the needs of these were in this respect different from those of the practising physician or surgeon, who required full information on which he might have solely to depend because of his distance from a good library or his ignorance of the language of the original article. Professor Lépine stressed the need for classification under clear subject-headings and for cross-references in the same journal to abstracts bearing on the same subject. He and his colleagues agreed with Dr. Leitch and the librarians in preferring that the author's name should come first in the bibliographical entry, and that this should be followed by the full title of the work in the original language. He laid special stress on the preparation of annual author and subject indexes to facilitate bibliographical research. To simplify the task of the user he considered it would be advantageous if a standardized method of arrangement of abstracts could be adopted by abstracting journals throughout the world. He advocated standardization of abbreviations and symbols used for metric units, chemical formulae, etc., and also adoption of the metric system in all scientific publications.

Dr. MARGUERITE LWOFF read an interesting paper on abbreviations, contractions, and symbols used in the medical and biological sciences. She differentiated between those accepted internationally and those peculiar to different countries, especially in the Anglo-Saxon world. Dr. Lwoff pointed out that

even with accepted international standards authors and editors used many variations. She gave as an example the abbreviations for the cubic centimetre, given variously as c.c., c.cm., and what she regarded as the illogical substitution of ml. In her view cm³ was the only correct and logical usage, but she realized she was fighting a losing battle against ml. She noted with regret that even French writers employed gr. as a contraction for gramme. Her recommendations that only recognized abbreviations should be employed, that the metric system should be generally adopted, and that local abbreviations should be avoided were endorsed by the committee.

Editing and Informing

Dr. G. M. FINDLAY, editor of *Abstracts of World Medicine*, gave the committee an interesting survey of the work already done by the Royal Society Conference on Scientific Information, and then went on to discuss abstracting from the point of view of the editor. He drew attention to the difficulty there was in finding out what medical and biological journals were actually being published in different parts of the world and to the difficulty, because of currency and other obstacles, even of obtaining those known to be published. Again, there was the problem of finding abstracters expert in a certain subject and also having a knowledge of the less common languages. An undesirable feature was the publication of the same article in more than one journal. Many of his observations bore out what Dr. Leitch had said about the faults of authors and editors. For example, tables were often presented in such a way that the reader could not deduce results of statistical significance and they did not always agree with what was in the text. The varying position of the contents list in journals increased the labour of those who had to select papers for abstracting. Dr. Findlay also criticized the number of different proprietary names for the same drug and the lack of uniformity in chemical terminology. References to previous literature were often incomplete or incorrect and the nomenclature of diseases was still in a chaotic state. He urged that a full list of medical and biological journals should be published and should be brought up to date at six-monthly intervals. He urged, too, that there should be full facility for the free interchange of medical and biological journals between different countries. The committee agreed with these views, and in general with his disapproval of the use of authors' abstracts. But it was pointed out that one of the strongest arguments in favour of authors' abstracts was the existence of the valuable journal *Biological Abstracts* edited by Dr. J. E. Flynn, who relied upon these very largely in the compilation of his useful periodical.

Dr. CHARLES WILCOCKS, director of the Bureau of Hygiene and Tropical Diseases, London, then gave an interesting talk on the use of the abstracting organization as an information service. He considered that accuracy rather than promptness should be the first consideration of the editor of an abstracting journal and that continuity of interest could be maintained only by continuity of editing. He described how the *Tropical Diseases Bulletin* and the *Bulletin of Hygiene* had evolved in response to needs, and how his bureau exchanged services with many other institutions. As examples of the invisible export of information he instanced the facts that his bureau provided a professor of industrial medicine with all the titles and articles on his subject, and extended a similar service to the Medical Research Council on toxicology.

Conclusion

The committee ended its three and a half days' conference by forwarding proposals to Unesco and making some recommendations which it is hoped will in time be adopted by abstracting organizations. It asked Unesco to publish a list of medico-biological journals with the system of abbreviations adopted by the *World List*. It also recommended that in such a list there should appear opposite the journal titles symbols to indicate which abstracting organizations included them in their survey. It asked Unesco to collect information on abbreviations and symbols used in medico-biological literature, and, having done this, to consider publication in a form suitable for use by abstracting services, editors, and scientists. It adopted the proposal made by Dr. Leitch for the method of arranging the

bibliographical entry to an abstract; urged that Unesco should continue its effort to promote the free interchange of medical and biological journals among different countries; advocated the universal use of the metric system for weights and measures and the centigrade system for recording temperatures in medical and biological communications; and advised the setting up of local advisory abstracting committees composed of editors and other representatives of abstracting agencies. It also recommended that editors of medical and biological journals should adopt greater uniformity in terms and greater precision in the papers appearing in their journals.

Those taking part in the conference were: Dr. H. Clegg; Dr. E. J. Crane, *Chemical Abstracts* (U.S.A.); Mrs. E. R. Cunningham, Medical Library Association (U.S.A.); Dr. G. M. Findlay, *Abstracts of World Medicine*; Dr. J. E. Flynn, *Biological Abstracts* (U.S.A.); Sir Herbert Howard, Commonwealth Agricultural Bureaux; Professor L. Justin-Besançon, Association de l'Enseignement Médical des Hôpitaux (France); Dr. L. Lampitt, *British Abstracts*; Dr. I. Leitch, Commonwealth Bureau of Animal Nutrition; Dr. M. Lwoff, *Bulletin de l'Institut Pasteur* (France); Dr. H. R. Viets, American Medical Association; Dr. Charles Wilcocks, Bureau of Hygiene and Tropical Diseases, London; Professor M. W. Woerdeman, *Excerpta Medica* (Netherlands). Also present as observers were: Dr. N. Howard Jones, Director of Library and Reference Services, WHO; Professor F. Verzar, University of Basle, for FAO; Dr. S. V. Larkey, Welch Medical Library, representing the Army Medical Library (U.S.A.); Dr. P. Lépine, Institut Pasteur (France); Professor R. V. Talice, Faculty of Medicine, University of Montevideo (Uruguay); Dr. A. Hann, International Federation for Documentation; and Mde. Duprat, of the Bibliothèque Nationale de Paris.

MEDICAL BIRTHDAY HONOURS

The names of the following members of the medical profession were included in a Birthday Honours List published in *Supplements to the London Gazette* on June 9:

K.B.E. (Military Division)

NEIL CANTLIE, C.B., M.C., M.B., F.R.C.S., Lieutenant-General, late R.A.M.C. Honorary Physician to the King. Director-General, Army Medical Services.

Knighthood

ARTHUR MARCELLUS DE SILVA, C.B.E., F.R.C.S., Member of the Public Service Commission, Colombo, Ceylon.

JOSEPH FRANCIS ENGLEDEU PRIDEAUX, C.B.E., M.R.C.S., L.R.C.P., Director-General of Medical Services, Ministry of Pensions.

HENRY SESSIONS SOUTTAR, C.B.E., D.M., M.Ch., F.R.C.S., Consulting Surgeon, London Hospital. Past-President of the British Medical Association.

C.B. (Military Division)

FREDERICK JOHN MURPHY, C.B.E., M.B., B.Ch., D.P.H., Air Vice-Marshal, R.A.F. Honorary Surgeon to the King.

KENNETH ALEXANDER MACDONALD TOMORY, O.B.E., M.B., Ch.B., Major-General, late R.A.M.C. Honorary Physician to the King.

C.M.G.

CHARLES NORMAN ATKINS, M.B., Ch.B., D.P.H., City Health Officer for Hobart, Tasmania.

CHARLES HERBERT HAMPSHIRE, M.B., B.S., F.R.I.C., Ph.C., Secretary, British Pharmacopoeia Commission.

JAMES GRANT SMITH TURNER, M.B., Ch.B., D.P.H., D.T.M., Colonial Medical Service. Director of Medical Services, Gold Coast.

C.B.E. (Military Division)

DAVID FETTES, O.B.E., F.R.C.S.Ed., Brigadier, late R.A.M.C. Honorary Surgeon to the King.

JAMES HAMILTON, M.B., Ch.B., Surgeon Captain, R.N.

C.B.E. (Civil Division)

CHARLES WORTHAM BROOK, Ph.D., M.R.C.S., L.R.C.P. For political and public services.

FRANCIS HENRY KNEHILL GREEN, M.D., F.R.C.P., Assistant Secretary, Medical Research Council.

THOMAS KEITH LYLE, M.D., M.Ch., F.R.C.S., M.R.C.P., Civil Consultant in Ophthalmology to the Royal Air Force.

ALEXANDER FLEMING WILKIE MILLAR, M.D., Chairman, Scottish Medical Practices Committee.

RALPH MONTGOMERY FULLARTON PICKEN, M.B., Ch.B., D.P.H., Provost and Mansel Talbot Professor of Preventive Medicine, Welsh National School of Medicine.

THOMAS EDMUND ALEXANDER STOWELL, M.D., F.R.C.S. For services to industrial medicine.

O.B.E. (Military Division)

WILLIAM VINCENT BEACH, F.R.C.S.Ed., Surgeon Commander, R.N.
EDWARD ALEXANDER RICE, M.B., B.Ch., Wing Commander, R.A.F.

O.B.E. (Civil Division)

ALBERT WILLIAM JOHN CRAFT, M.R.C.S., L.R.C.P., Principal Medical Officer, Ministry of Pensions.

KIRIKANKANANGE JUSTIN DE SILVA, L.M.S., J.P. For public services in Moratuwa, Ceylon.

JOSEPH ELLUL, M.D., F.R.C.O.G., Professor of Midwifery and Gynaecology, Malta.

JOSEPH HUBERT FERNANDO JAYASURIYA, F.R.C.S., Senior Surgeon, General Hospital, Colombo, Ceylon.

ALEXANDRA MARGARET ANNE JOY, M.B., B.Ch., for services as medical practitioner in the isolated area of Lake Grace, Western Australia.

THOMAS PERCY REES, M.D., M.R.C.P., D.P.M., Medical Superintendent, Warlingham Park Mental Hospital, Surrey.

ARUMUGAM VISWALINGAM, L.M.S., lately Ophthalmic Specialist, Malayan Medical Service.

NOEL EVERARD WATERFIELD, M.B., F.R.C.S., County Director, Surrey Branch, British Red Cross Society.

EDWARD MILNS BANBRIDGE WEST, B.M., B.Ch., Chief Officer, African Affairs Department, Southern Rhodesia.

WALTER GERALD WICKREMasinghe, M.R.C.S., L.R.C.P., Acting Director of Medical and Sanitary Services, Ceylon.

GERALD RICHARD COURTENAY WILSON, M.R.C.S., L.R.C.P., Acting Senior Medical Officer, Tanganyika.

Honorary O.B.E. (Civil Division)

HO KO TSUN, Medical Officer in charge of the Eastern Chinese Public Dispensary, Hong Kong.

M.B.E. (Military Division)

ROBINA MARY DUNCAN MORRELL, M.B., B.S., Major, R.A.M.C.

M.B.E. (Civil Division)

MAURICE PENNEFATHER BROWNE, M.R.C.S., L.R.C.P., D.T.M.&H., Colonial Medical Service, Medical Officer, Gold Coast.

JOHN MINTO FITTON, M.B., F.R.C.S., Orthopaedic Surgeon, Mauritius.

ARTHUR GEORGE TEASDALE MATTHEWS, Medical Officer at His Majesty's Agency and Consulate at Muscat, Arabia.

WILLIAM GEORGE ROSE, L.R.C.P.&S.Ed., Medical Officer for Eastern Districts, Southern Rhodesia.

The following appointments also appeared in the Honours List: *Order of Merit*, Sir Robert Robinson, M.A., LL.D., D.Sc., President of the Royal Society since 1945. *D.B.E.*, Miss Harriette Chick, C.B.E., D.Sc., for services to the study of nutrition. *O.B.E.*, David Garnet Davey, M.Sc., Ph.D., and Francis Leslie Rose, Ph.D., F.R.I.C., for their services in the discovery of paludrine and antrycide.

LADY TATA MEMORIAL TRUST

INTERNATIONAL AWARDS FOR RESEARCH IN BLOOD DISEASES

The trustees of the Lady Tata Memorial Fund announce that, on the recommendation of the Scientific Advisory Committee in London, they have made the following awards for research in blood diseases, with special reference to leukaemia, in the academic year beginning on Oct. 1, 1949. *Grants for research expenses and assistance*: Dr. Marcel Claude Bessis (France), for work in Paris; Dr. Jörgen Bichel (Denmark), for work at Aarhus, Denmark; Dr. Pierre Cazal (France), for work at Montpellier; Dr. Johannes Clemmensen (Denmark), for work in Copenhagen; Dr. Endrev Kelemen (Hungary), for work at Szeged; Dr. Jagdish Chandra Mehta (India), for work at Agra; Professor Charles Oberling (France), for work in Paris; Dr. Edith Paterson (Great Britain), for work at Manchester; Dr. Günther Schalloek (Germany), for work at Münster; Professor Edoardo Storti (Italy), for work at Pavia. *Scholarships*: Dr. Pascou Atanasiu (Rumania), for work in Paris; Dr. Claus Frederik Munk Plum (Denmark), for work in Copenhagen.

Nova et Vetera

A COLOURFUL VICTORIAN

The memory of all but the very greatest surgeons is necessarily brief. Their achievements, like that of actors and musicians, flow into the general ocean of culture and, like ripples, are soon lost to vision. The achievements of even the greatest surgeons cannot be transmitted intact to the generations that follow, as can that of the poet or the sculptor. Nevertheless, though their work has no lasting memorial, their deeds become an integral part of social history. Their age cannot be represented by the social historian unless he understands what certain of them have sought to do, have done, and have failed to do.

We have perhaps hardly reached the stage at which a social history of the nineteenth century can be constructed on scientific lines, but in due course the historian will need a few sample lives of surgeons of the period. Dr. Flack¹ has produced a most readable and exactly documented account of a very typical surgical figure of the period. It is worth immediate note that during Lawson Tait's active years the Listerian antiseptic system began to be displaced by aseptic methods. Much of Lawson Tait's combativeness found outlet in opposing Listerian methods for reasons partly good but partly irrational and indeed nonsensical. Nevertheless, as Dr. Flack most interestingly shows, Tait, a blind prophet, was quite unconsciously adumbrating asepsis.

Seeking a word for Lawson Tait, none comes better than the journalistic neologism "colourful." His life was so full of tints—varied, lively, and often crude—that Dr. Flack has difficulty in enumerating them all. Tait, in fact, would make a good hero for a novel or melodrama, for his were passions so violent, instincts so valid, skill so transcending, skin so thick, and emotions so strong that his character shows up with peculiar vividness against the humdrum background of Victorian provincial life. It cannot be denied that he has influenced deeply the science and art of surgery as well as the general development of medical practice. Specifically, he did more than any man to establish gynaecology as a specialism, he founded the Medical Defence Union, he introduced many improvements in surgical technique, he raised the standard and status of the provincial consultant, he set a new standard of case-recording, he started asepsis on its victorious way, and he was one of the first to see the need for the special training of the surgeon as artist and craftsman.

These are among the achievements of a man whose life was effectively ended before he was 50. But it is much more pleasant to read about this turbulent genius in the well-written narrative of Dr. Flack than it must have been to live and work smoothly with him through the years. This is a type of surgeon that could have existed only in the medical atmosphere of the later nineteenth century. None of us will see his kind again. Any who would like to know what sort of men surgeons were in those days cannot do better than turn to Dr. Flack's lively and often exciting pages.

CHARLES SINGER.

¹ *Lawson Tait, 1845-1899.* By I. Harvey Flack, M.D. (Pp 143; illustrated. 17s 6d) London: William Heinemann Medical Books 1949.

The twenty-first annual meeting of the Medical Insurance Agency was held on June 1. The report of the committee of management for 1948 recorded another successful and busy year. Grants to the principal medical and dental charities were sanctioned amounting in all (by use of the covenant system) to close upon £14,000. Progress in all branches of the Agency's business in 1948 was marked, though the figures for new life business were somewhat below the total for 1947. A branch office was set up in Leeds in the autumn of 1948, and another branch has recently been opened in Manchester. The full impact of the National Health Service upon the needs of the medical profession has not yet been felt; but the special facilities which the Agency is now able to negotiate for loans towards the purchase of houses, cars, or equipment have already been taken advantage of widely and have replaced loans for the purchase of practices. Lord Horder, Sir Henry Tidy, Dr. Alfred Cox, Dr. James Fenton, Mr. A. M. A. Moore, and Mr. R. W. Raven were re-elected to the committee for three years; Dr. Oliver Scott was elected to replace the late Dr. Bone. Dr. James Fenton was re-elected chairman and Dr. Henry Robinson honorary secretary.

Preparations and Appliances

A NEW SURGICAL SUCTION PUMP

Mr. DAVID AIKEN, surgical chief assistant, Royal Hospital, Sheffield, writes: The methods employed for producing suction have included water-pumps (the least efficient), steam pumps, and electric pumps of reciprocating or rotary type. The latter have enjoyed the greatest popularity, but it is not certain that those available were the best for theatre work. We have investigated several industrial pumps, and one of these, the Mono pump, was found to outclass the modern surgical suction pump on account of its reliability, simple design, easy maintenance, and low initial cost.

The apparatus (see illustration) is of such sturdy construction that material accidentally aspirated into the pump does no harm

Sectional arrangement of the Mono pump, embodying (1) suction branch; (3) stator; (5) rotor; (10) universal drive from the main shaft.

and causes no loss of the normal vacuum of 28-30 in. (71-76 cm.) of mercury. Complicated valves to prevent aspiration into the pump are therefore eliminated and, furthermore, the nurse no longer dreads the consequences of allowing the collecting-bottle to overflow during operations or when cleaning out the tubing. Long delays for repairs are obviated and irritating failure of the suction during operations no longer occurs.

A single rotor, rolling in a fixed stator, constitutes the mechanism of the Mono pump. The stator, which is normally of rubber, is in the form of a double internal helix; the rotor is also of helical design, but with a single scroll and with half the pitch of the stator, producing a uniform and positive displacement.

This original and simple principle has produced a pump which embodies a single rotating element without valves, gearing, or lubricators; therefore maintenance charges are reduced to a minimum and skilled attention becomes unnecessary. The rubber stator may require replacement after 4,000 hours' continuous working, but it costs only nine shillings and can be quickly and easily fitted.

The size or capacity of the pump is governed by the number of theatres to be supplied with suction. For theatre work one large unit is neither as economical nor as reliable as numerous small units, and therefore it is recommended that each theatre be equipped with a separate unit. Mono pumps A2 and A2 L, with a displacement of 150 and 300 gallons (680 and 1,360 litres) per hour respectively, will be found the most useful sizes. The A2 L provides a most vigorous suction because of the large minute-displacement. For simplicity, for noise elimination, and in order to lessen the likelihood of igniting the explosive anaesthetics, the operating theatre should be kept free of any electrical equipment that can be placed in an adjoining room without inconvenience to the operator or his staff. This especially applies to suction pumps, which should be installed in a near-by room or basement and connected to the theatre by pipes.

For the past eight months two Mono pumps have been used in each of our busy theatres; they have given every satisfaction and required no attention whatsoever.

I wish to thank Messrs. Mono Pumps, Ltd., Mono House, 67, Clerkenwell Road, London, E.C.1, makers of the pump, for their help.

Correspondence

Cancer of the Cervix

SIR,—In his very interesting article (June 4, p. 978) on the incidence of cancer of the uterine cervix Mr. R. G. Maliphant says, "In spite of the efforts expended in educating the public on cancer, etc." I shall be greatly interested to hear where in the British Isles this effort has been made. It seems to me that the only method by which the public can be instructed concerning the symptoms of cancer, and at the same time fear of the disease allayed, is to train a very large number of lay people who would instruct small groups of other lay people.

At one time I had hoped that such an experimental scheme would be undertaken by the British Empire Cancer Campaign in a limited area, but this is now very improbable, because it appears that certain members of the campaign consider that lay people should only be instructed by qualified medical practitioners. Apart from the impossibility of finding enough doctors with sufficient time to instruct millions of people, it is difficult to see how it would be possible to prevent the lay audiences from passing on the information received from the doctor to other lay people, which is precisely the point to which objection has been taken.

In the second paragraph of Mr. Maliphant's article there seems to be some confusion of thought concerning time and the stage of the disease. Surely it is probable that all malignant growths of the cervix give rise to bleeding approximately at the same time after the onset of the disease, but in the case of rapidly growing undifferentiated tumours the disease has already reached stage IV, whereas the slow-growing differentiated tumour is still stage I. Whether it is true to say that "early cervical cancer is usually symptomless" depends on a definition of "early." In a series of 859 cases of cancer of the cervix it was found that 54.5% of the patients had noticed irregular bleeding for more than three months before going to see a doctor and, included in these, 33.7% waited more than six months and 14.9% over twelve months. There is therefore plenty of scope for lay education if somebody can be found to undertake the job.—I am, etc.,

London, W.1.

MALCOLM DONALDSON.

SIR,—The excellent paper on the incidence of cancer of the uterine cervix by Mr. R. G. Maliphant (June 4, p. 978) prompts me to plead for two aspects of health education which I submit have neither won the response of the public nor have had the attention paid to them which their individual importance merits.

1. The attendance at post-natal clinics is, in my experience, poor. Those who do attend once seldom come up for examination again. The ravages of child-bearing—and I am sure the morbidity is greater than we care to admit—may well be glossed over, or may not be manifest when a patient is examined four or six weeks after confinement. I would like to see health propaganda concentrating on a second and much later examination at, say, six or nine months.

2. Mr. Maliphant has shown that in the series investigated 34.7% occurred in the age group 45–54. The encouragement to women to undergo gynaecological examination at the menopausal years would evidently show up early stages of cancer which in a relatively short time might well have been classified as beyond hope.

Finally, Sir, I would stress the fact that the gynaecological and even general examination undertaken at these two "danger periods" would establish not only the incidence of this particularly insidious cancer but the concomitant varieties which in their train bring the same tragic result.—I am, etc.,

Princes Risborough, Bucks.

F. H. M. DUMMER.

Infective Hepatitis and Portal Cirrhosis

SIR,—The paper by Major K. Damodaran (June 11, p. 1032) contains a general statement on the "unreliability of liver-function tests in estimating the severity of infective hepatitis" which hardly appears to be justified by the facts given. This statement would appear to depend upon a single fatal case of

hepatitis with negative flocculation tests and a normal serum alkaline phosphatase.

Now it is well recognized that neither of these procedures are really liver-function tests in the strict sense, but merely indications of a certain type of disturbed liver metabolism. They are of particular value in the differential diagnosis of jaundice and are frequently of value in hepatitis, but it has never been claimed that they are specifically related to liver-cell damage. The serum alkaline phosphatase is often normal in infective hepatitis, and about 7% of cases have negative flocculation tests throughout.

It is, therefore, obviously unwise to depend entirely on tests of this type in attempting to assess the severity of cases of hepatitis. For this purpose one would also need to estimate serum bilirubin, albumin, and globulin, and to examine the urine for excess of urobilinogen. I have never seen a patient dying of hepatic disease with normal values for all these tests, and would suggest that Major Damodaran should try a more suitable battery of tests before dismissing them as useless for his purpose.—I am, etc.,

London, S.W.1.

N. F. MACLAGAN.

Perforations of the Oesophagus and of the Rectum

SIR,—The communications by Mr. Leslie J. Temple and Mr. J. D. T. Jones (May 28, pp. 935 and 933) on these injuries are timely and useful. I doubt if the risks of oesophageal instrumentation are yet sufficiently appreciated; only a few months ago yet another case came under my notice. It is a great satisfaction and encouragement to me to read of the successful management of some of these erstwhile tragedies, for when they were regarded to be almost invariably fatal I enunciated what I considered reasonable principles for their treatment. These rules were detailed in my George Halliburton Hume Lectures in 1943 and were set out in the brochure on *Injuries and Diseases of the Oesophagus* published in 1946.

It is distressing to read of the rectal injuries following the administration of enemata. I note that the bone nozzle is blamed, but the lack of appreciation of the direction of the anal canal, the paucity of lubricant, and the neglect of the significance of the production of pain are the real factors.

In the year 1904 it fell to my lot to use for the first time the second of the aerosigmoidoscopes imported into this country, but from lack of training and experience in its use my attempts were *mal à propos* and the pelvic colon was perforated in two places, with fatal consequence. I have often referred to that accident and have many times exhibited the specimen, and in my presidential address in 1926 to the Subsection (as it then was) of Proctology of the Royal Society of Medicine the case was reported in full.¹

Hermann Strauss, who devised and introduced the aerosigmoidoscope to the profession, laid it down as imperative that as soon as the extremity of the instrument had negotiated the anal canal further advance must only be carried out under the guidance of the eye. If that was always regarded as the golden rule, accidents would be very infrequent.—I am, etc.,

Taplow, Bucks.

Treatment of Perforations of the Oesophagus

SIR,—In his article on perforations of the oesophagus (May 28, p. 935) Mr. Leslie J. Temple allows me credit for demonstrating that endoscopy perforations of the pharynx and oesophagus in the cricoid region could be successfully treated by suture. I had hoped that I had done more than this and had also argued a convincing case for the adoption of *immediate* suture in *all* such injuries as the treatment of choice. For that reason I regard as most unfortunate his qualified advocacy of an initially expectant attitude towards suspected perforations of the cervical oesophagus.

I fear that some readers may overlook the fact that the perforation in his case so treated was not associated with surgical emphysema and therefore not actually proven clinically to extend through all coats of the oesophageal wall, however definite it may have seemed at oesophagoscopy. The circumstances, therefore, are different from those obtaining in the average perforation after

the development of cervical emphysema. In other words, extravasation is already occurring by the time the diagnosis is made. To treat this type of case conservatively in the first instance, relying on intensive chemotherapy to prevent or limit infection instead of resorting to immediate suture, is in my opinion strongly to be deprecated for the following reasons.

(1) Clinically it is extremely difficult to distinguish between uncomplicated surgical emphysema in the neck and emphysema with superadded cellulitis. It must be appreciated also that under the influence of gravity infection may spread rapidly downwards behind the oesophagus into the posterior mediastinum before the lateral parts of the neck are seriously involved. The result is that the clinician who embarks on conservative treatment may well be deluded for two or three days into believing that the condition is under control by chemotherapy when in fact a dangerous mediastinitis has already become established.

(2) While suture of the pharyngo-oesophageal wall within a few hours of the perforation is technically easy and a very satisfactory closure is obtained, it is quite otherwise once infection has occurred. The tissues then become oedematous and friable, and stitches tear out, so that surgical repair is no longer feasible and drainage alone can be performed.

Many patients, perhaps the majority, with post-cricoid endoscopy perforations will undoubtedly recover under conservative treatment, but there are equally certainly others who can only be saved by operation. I know of no means by which one can predict the outcome of expectant treatment with confidence, and therefore I maintain that the only safe course is to operate on all cases without delay, at a time when the ideal of immediate suture can still be practised. Under this scheme admittedly some patients will be submitted to an unnecessary intervention, but as the operation is a relatively simple one, unlikely to carry any intrinsic operative mortality, no serious objection can be supported on this ground.

A further advantage of immediate operation is the peace of mind and certainty of recovery that it brings—a state of affairs that contrasts strikingly with the anxieties, complications, and doubts associated with an expectant regime. I have treated two gastroscopy perforations by immediate suture, and the post-operative convalescence has been astonishingly smooth and uneventful; so much so indeed that in the second case we were actually able to proceed to a partial gastrectomy for his gastric ulcer four days later.—I am, etc.,

London, W.1.

J. C. GOLIGHER.

Continuous Irrigation in Prostatectomy

SIR,—The letter of Mr. H. D. Moore about continuous irrigation after prostatectomy (May 28, p. 958) prompts me to draw the attention of your readers to a most satisfactory two-way irrigating catheter invented by Mr. E. G. Tuckwell. For those wishing to make use of a two-way catheter after the Millin type prostatectomy the Tuckwell catheter will prove extremely satisfactory; it is manufactured by A. W. Hawkins and Co., Ltd., 15, New Cavendish Street, W.1, and was described in the *Lancet* (1946, 2, 94).—I am, etc.,

Radlett, Herts.

REGINALD S. MURLEY.

London Lock Hospital

SIR,—It is inconceivable that, following the discovery of streptomycin, or, indeed, of any drug that was found to have a beneficial result in the treatment of tuberculosis, the Brompton Hospital, for instance, should promptly be closed and the patients transferred to local clinics and the care of tuberculosis officers just because the disease could be more rapidly cured or arrested.

This, however, is precisely what has been suggested to the North-West Metropolitan Regional Hospital Board in the case of the London Lock Hospital (*Journal*, May 28, p. 948). There appears to be so much confusion in the minds of many doctors as well as the laity that the modern improved methods of treatment of venereal diseases require only routine diagnosis and treatment, and that these can be carried out in out-patient departments. It is frequently presumed that painful complications can always be avoided.

As one who has had the honour of serving the Lock Hospital for over twenty-five years, it has been possible to observe the different types of case and the methods of treatment that have indeed radically changed. Twenty-five years ago the

majority of female patients were admitted either because they were destitute and had little chance of obtaining work while ill or because they came from a distance and had no opportunity for treatment near their homes. These groups may be considered as having occupied "hostel" rather than "hospital" beds. The necessity for the provision of beds for this class of patient has practically disappeared, as they can be rapidly rendered non-infective, and then can at once obtain work if they wish, as the demand for female labour exceeds the supply.

In 1923, however, there was a group of patients who are similarly with us to-day. They are men and women who have extension of their diseases causing pain and disability, and those on whom varying methods of treatment (some new and some old) require to be tried out under the direct observation of the specialist who has seen them in the out-patient department. It is of paramount importance for the retention of the confidence of the patient and for the most efficient treatment that he or she remain under the direct care of the same consultant both in the out-patient and in-patient departments. Careful clinical research is often only possible when the patient can be admitted into hospital.

Nowadays what is really required is a small number of hospital beds staffed by experienced specialists who are responsible for both the in-patient and out-patient care. This is the present policy of the medical staff of the London Lock Hospital.—I am, etc.,

London, W.1

G. M. SANDES.

Resectable Carcinoma of the Stomach

SIR,—Cancer is now second in command of the "men of death" in England and Wales, Scotland, Northern Ireland, and Eire, and in the United States of America. All the home countries show an almost steadily increasing mortality from cancer from 1937 to 1946. Comparing 1937 with 1946, England and Wales (per 1,000 of the population) show an increase of 0.14, Scotland 0.23, Northern Ireland 0.12, and Eire 0.10. In round numbers, in England and Wales the annual deaths from cancer were 70,000 for the years 1940-2. The figures for the last completed triad of years, 1944-6 (74,000 annual deaths), are still more alarming.

The stomach is the commonest seat for the primary growth in the male, and runs a close second in females to mammary cancer. Against gastric carcinoma physiotherapy, including x rays and radium, and the most modern therapeutics are of no avail. Can surgical intervention be of any definite aid? Harnett¹ states that, of 1,405 patients with cancer of the stomach treated in the London hospitals in 1938-9, only 56 (4.03%) survived for five years. Pack and Livingstone² contend that, if every patient with cancer of the stomach were to enter the best surgical clinic in the world, about 95% would be dead of the disease within 18 months.

But there is another and a less depressing side to the question. In 1937 Professor John Morley³ stated that of 58 gastrectomies for malignant disease of the stomach one was alive and well 13½ years after the operation, but in 1949⁴ he reported that of 110 survivors from resection five were alive and well after 20 years and one after 11 years. In the Mayo Clinic⁵ between the years 1907-39, 2,772 cases of gastric carcinoma were subjected to resection. Of these, 2,342 survived the operation and were thus given a chance of cure. Of this group 28.9% lived for five years or longer, 20.4% lived for ten years or longer, 15.2% lived for fifteen years or longer, and 6.3% lived for twenty-five years or longer.

The following three cases are briefly abstracted from a fuller report as successful examples of resection, and with a view to contradicting statements made in a recent surgical textbook: (1) that the examination of the gastric juice by test meal is usually valueless, for by the time free hydrochloric acid is absent the disease will be inoperable, and (2) that the presence of a palpable tumour is a late sign and usually indicative of advanced disease too late for resection.

Case 1.—A man aged 30 years. Admitted to the Royal City of Dublin Hospital on March 11, 1906. Profoundly anaemic, gastric contents contained no free hydrochloric acid; the faeces had latent blood. There was a palpable tumour in the epigastrium. Operation (Jameson Johnston) on April 3, 1906; tumour excised and posterior gastro-enterostomy performed. Discharged May 30, 1906.

A letter from him on Aug. 28, 1948, states: "I am happy to let you know I am very well at present, can eat and work very well and do all the work which I have to do." Specimen sent to pathological department, Trinity College, was reported as a typical pyloric carcinoma.

Case 2.—A man aged 51. Admitted to hospital Feb. 2, 1934, with shortness of breath, lightness in head, and weakness of legs. On palpation, a large mass was felt in the left hypochondrium and epigastrium. Blood (Dr. Harvey): Hb 51%; R.B.C. 3,250,000 per c.mm.; W.B.C. 47,220 per c.mm. (polymorphs 95%). Fractional test meal: No free hydrochloric acid. X-ray examination (Dr. Hardman): "Large carcinomatous growth involving the posterior and probably the anterior wall of the stomach in pars media. Gross filling defect coincides with a palpable tumour." Operation (Mr. Seton Pringle) on March 2, 1934: "Stomach was found to have a large fungating carcinoma involving extensively the posterior wall of the stomach. Partial gastrectomy performed with removal of two-thirds of the stomach; end-to-end anastomosis made (Polya I)." Blood count on March 8, 1934 (Dr. Harvey): W.B.C. 9,160 per c.mm. Discharged on March 12, 1934. A slight touch of bronchitis brought him to the extern department in October, 1948. Report on a barium meal administered on Oct. 21, 1948, 14½ years after his operation (Dr. Hardman): "The opaque meal demonstrated a gastric sac about half the size of a normal stomach. It emptied freely through the anastomosis, and there was nothing to suggest any recurrence of the carcinoma."

Case 3.—A man aged 67. Admitted on May 31, 1934, complaining of soreness and wind in the stomach, loss of appetite, weakness, pallor, and wasting. Examination of abdomen negative. Fractional test meal: No free hydrochloric acid. Faeces positive for occult blood. X-ray report (Dr. Hardman): "There is a well-defined and extensive filling defect involving both the lesser and greater curvatures in the upper part of the stomach, but not so high as the fundus. The lower half of the stomach is normal radiologically, and there is no gastric stasis. X-ray appearances justify a positive diagnosis of carcinoma, and the growth is probably above the level of the costal margin and therefore not palpable." Operation on June 9, 1934: Mr. Pringle removed a large portion of the stomach; posterior gastro-enterostomy was performed. Discharged in very good form on July 30, 1934, two months after his operation. He attended the extern department of the hospital frequently for bronchitis, and Dr. Hardman on May 11, 1944, gave the following report after a barium meal: "The remaining gastric sac is small, but there is no gross filling defect involving either curvature which would justify a diagnosis of recurrence." He is now at least 82 years of age. The specimens in Cases 2 and 3 were sent to the pathological department, Trinity College, Dublin, where Professor O'Meara reported that they were both adenocarcinomas.

It is hoped that the publication of the above cases may do something to minimize the pessimistic view held by many physicians and surgeons of the almost hopelessness of a radical cure in gastric carcinoma. If we physicians can recognize gastric carcinoma before secondaries form, resection offers a reasonable prospect of complete recovery.—I am, etc.,

Dublin.

Partial Gastrectomy

SIR,—I have found Mr. John Hosford's paper entitled "Some Aspects of Partial Gastrectomy" (May 28, p. 929) most interesting and highly instructive, and his analysis of the various techniques with their respective percentages of excellent, satisfactory, or bad results is exactly what is wanted by the younger surgeon of to-day, for he is by no means rarely left with some doubt in his mind which of the various techniques to follow. For the average surgeon, carefully selecting his ulcer patients for operative treatment, it takes a relatively long time to collect and to follow up a sufficiently large number of cases upon which to base his own definite opinions, and Mr. Hosford ably fulfils this want.

Mr. Hosford does not state if he is, as a result of this investigation, going in future to favour any one type of gastrectomy, or perhaps, feeling as he does that it really matters very little, he has no fixed views on the subject. It would also be very instructive to learn if Mr. Hosford encountered any instance of post-gastrectomy anastomotic ulcers in the present series under discussion. It would appear that the figure of 5% is too high for a properly performed partial gastrectomy. As regards the antecolic anastomosis with the afferent loop to the

greater curvature, I had always understood this was the one type of anastomosis which gave rise to more post-operative vomiting than any other, and I note there are only six cases in this category.

Mr. Hosford's over-all mortality of 0.5% is exceedingly low, covering as it does a considerable period prior to the introduction of penicillin, which for the bad-risk chesty patient does seem to decrease the incidence of post-operative complications. It is a figure which can hardly be bettered.—I am, etc.,

Barnsley, Yorkshire.

ANDREW G. BUTTERS.

Diaphragmatic Hernia and Anaemia

SIR,—The paper by Professor A. D. Codounis (May 7, p. 805) on diaphragmatic hernia associated with anaemia is of special interest to me, as I have under my care a boy aged 7, weighing 3 stone 3½ lb. (20.5 kg.), with the following history.

According to his mother, he has been pale and apathetic since infancy; following an influenza-like illness three months ago these symptoms have been more marked. He has at no other time suffered from chest or gastro-intestinal symptoms and has always eaten a normal mixed diet. There is no family history of anaemia.

I first saw him about six weeks ago, when, apart from the extreme pallor, there were no abnormal physical signs. He was admitted to hospital, and special investigations revealed haemoglobin 35% (Sahl), red blood cells 2.96 million per c.mm., colour index 0.6, mean cell volume 50 c.μ, white cell count normal, red cell average thickness 1.1 μ, fragility normal. Chest radiography was undertaken by Dr. Stanley Nowell, who reported on a straight film: "There is an opacity lying behind and to the right side of the heart shadow, which extends upwards to the lower border of the hilum and contains a fluid level. Examination on swallowing barium shows that the opacity is a large gastric hernia through the mid-portion of the diaphragm, the oesophagus entering the stomach below its upper border on the medial side and one inch (2.5 cm.) above the diaphragm."

Stool examinations revealed the presence of occult blood in some specimens, and an alcohol-histamine fractional test meal gave a normal curve for gastric acidity.

The child was treated with full doses of iron, and a blood picture two weeks after the original one showed a rise in the haemoglobin to 58%, red blood cells 3.74 million per c.mm., and colour index 0.8. Re-examination of the chest after the radiological report had been seen showed very slight diminution of air-entry at the right base behind (easily missed, as in this case). Drinking half a pint of water failed to make the signs more definite.

I consider that the anaemia, in this case at least, is due to compression, probably intermittent, of the gastric veins as they pass through the defect in the diaphragm. This would give rise to venous congestion and oozing of blood into the herniated portion of stomach. Long-continued chronic blood loss may eventually result in marrow exhaustion and an aplastic type of anaemia. May not this be the explanation of the macrocytic phase in Professor Codounis's case?—I am, etc.,

Wrexham, Denbigh.

P. R. C. EVANS.

Dystocia after Amputation of Cervix

SIR,—Your correspondents have, I think, proved one of the points of my memorandum: that dystocia may follow amputation of the cervix (if, indeed, this point were ever in doubt). With respect, however, I suggest that Dr. George W. Kosmak (May 7, p. 823) has missed the main point, which was that untoward results of frequently performed operations should be recorded. The amputation of the cervix to which I referred is that which is an integral part of the Manchester operation for prolapse, carried out daily by most gynaecologists. The Sturmdorf procedure is well known and used in this country, though many prefer Bonney's amputation, of which the former is a modification. Neither, however, is so commonly used, nor could replace, the guillotine amputation, the importance of which former generations of Manchester gynaecologists have shown in the treatment of prolapse.—I am, etc.,

Manchester, 3.

W. CALVERT.

Persistent Amnesia

SIR,—In their interesting article on amnesia (May 28, p. 938) Drs. R. E. Hemphill and J. R. Stuart state they are not aware that electric convulsion therapy has been applied before in the treatment of this condition. They are in doubt as to whether

genuine psychological amnesia persisting for years has ever occurred. Please allow me a word about an unidentified man whose loss of memory baffled many psychiatrists during and after the North African campaign.

This man was first seen on May 8, 1943, at a front-line New Zealand field ambulance (214). He had no identity papers, but papers from a torn diary indicated he had a recent emotional upset. He was evacuated to a New Zealand base hospital as a case of hysterical stupor due to "the effects of battle stresses on an overwrought mind." He was mute and unresponsive, required to be spoon-fed, and had gross tremors of the right arm and shaking of head. Following intravenous barbiturate treatment his tremors disappeared and the stuporous state subsided, but a complete amnesia for his personal life remained. He was transferred to a British psychiatric hospital (41 General), where hypnosis, narco-analysis, and electric convulsion treatments were given on several occasions without benefit. He was an intelligent man (matrix S.G.1), who worked extremely well in the ward and showed no sign of abnormality apart from amnesia for his personal life. His photograph was circulated in New Zealand and British papers without result, and he was eventually evacuated to the United Kingdom as an unidentified British subject. Six months ago he was reported to be working in the North of England. Loss of identity still persisted—I am, etc.,

Dublin

F. McLAUGHLIN.

Dried Plasma for Domiciliary Midwifery

SIR,—It is assumed by Dr. C. T. H. Whiteside (June 4, p. 1005) that a transfusion of plasma may be a life-saving measure in cases of retained placenta with post-partum haemorrhage, the placenta being removed later in hospital. Undoubtedly many patients do not die under this regime, but it should never be condoned on that account.

I do not wish to discuss the possible dangers of plasma transfusion, the superiority of whole blood in cases of recent haemorrhage, or the efficient organization of obstetric "flying squads" and regional blood transfusion services, which will often allow transfusion to be given in the home at very short notice. I wish merely to reiterate that the correct treatment of the abnormal third stage of labour is the removal of the placenta without delay. This will usually involve a manual removal, which requires no special equipment beyond sterile elbow-length gloves (or gloves and a sterile gown), and is truly a life-saving operation if performed before the patient is in *extremis*. It is not sufficiently realized that a retained placenta may produce shock out of all proportion to the blood loss, and the rapid improvement in condition following delivery of the placenta must be seen to be believed. If every placenta were out within two hours there would be few, if any, maternal deaths in the third stage of labour.

Every obstetrician who has worked with "flying squads" must have marvelled at the readiness of practitioners to undertake difficult forceps extractions under relatively deep anaesthesia and at their obvious reluctance to remove a placenta—an operation often done under 0.2 or 0.3 g. of thiopentone. I believe the explanation lies in the fact that experience of the former can be gradually acquired in practice, both as an onlooker and through the medium of easy cases. The first time the hand is plunged into the uterus in search of the placenta is an awful experience, and one that is best encountered in the helpful atmosphere of a training hospital. Until domiciliary obstetrics is largely performed by those with post-graduate training, so long will there be a greater demand for plasma than for sterile gloves.—I am, etc.,

Birmingham, 15.

W. G. MILLS.

Care of the Elderly

SIR,—It is a complete fallacy, in my experience, to say that an elderly patient is of necessity more troublesome to a doctor than a young one, and that, were he compelled to reduce his list of N.H.S. patients, a doctor would naturally try to get rid of his elderly patients.

So far as I am concerned, patients between the ages of 70 and 90 (and older if needs be) are always accepted. By the time they have reached the age of 70 many have steered with a fair degree of safety between the Scylla of carcinoma and the

Charybdis of cardiovascular disease. Furthermore, they are no longer harassed with the phobias and obsessions which often perplex and confuse the minds of the young and middle-aged. Added to that, old people have a great fear of being sent to bed, and therefore do not summon the doctor for trifles. "Folks die in bed," they so often say, half humorously and half pathetically.

To those who have an innate sympathy and love for those who have passed through the fires of life, the care of old people is often its own reward. Unfortunately this is not always the case, even among members of their own families, to whom they are frequently a nuisance, and sometimes a source of discord between husband and wife.

Old people cling to their own home, even if it is a single room, and if only a little domestic assistance could be procured for them to keep such rooms clean and to do a little simple cooking and their shopping many of these old people could carry on. They would also be relieved of that sense of complete isolation which many of them must feel, and this occasional intercourse with other human beings would save them from falling into oddities of behaviour.

Unfortunately many old ladies living alone seem to be impregnated with an aroma of paraffin oil, which follows them wherever they go; this is a very potent testimony to the dangers to which they expose themselves and to scanty meals cooked over a small oil-lamp. It is scarcely surprising that so many old people seem to live on bread and jam, and suffer from avitaminosis (see *Journal* of May 14, p. 863). Under present economic and rationing conditions many of them can scarcely do otherwise.—I am, etc.,

Hove Sussex

G. L. DAVIES.

Anthisan Poisoning

SIR,—I wish to report a rather unusual case. A child aged 21 months accidentally swallowed six 100-mg. tablets of pyranisamine maleate ("anthisan"). Approximately two hours after the child had taken the tablets she lost consciousness. This was accompanied by a profuse catarrhal discharge from the upper respiratory tract and epileptiform convulsions. Gastric lavage and continuous administration of oxygen had no effect on the child's condition. She died three-quarters of an hour after the onset of loss of consciousness. Post-mortem examination revealed general toxic changes throughout the body.

I consider this case worthy of note, as there does not appear to have been a similar one reported.—I am, etc.,

Morley, Yorks.

MAURICE TORIAS.

POINTS FROM LETTERS

Adoption of Children

MISS ANNE ASHLEY writes from the Edinburgh Council of Social Service: The case referred to by Dr. G. G. Jones (May 21, p. 912) is not an isolated one. The fact that such cases do arise is among the reasons why such very great care is needed not only in arranging adoptions but in encouraging a child's mother or relatives to assume that it can be suitably provided for in this way. It is not only children who are legally adopted who may be in a most unhappy position if they prove afterwards to be unsuited physically or mentally, or if the adopters have not sufficient stability to maintain their attitude of responsibility and affection towards the child whenever difficulties arise; there are also children whose unfitness becomes apparent before the adoption goes through, but who have already been taken into the care of the prospective adopters and are accordingly handed back by them. In the meantime the mother and her relatives, having handed over the child, will have been encouraged to assume that it is provided for for life, and are likely to be far less prepared to rise to the responsibility, which is still theirs, for the child's proper care than if they had been encouraged to accept this primary obligation from the beginning. Many social workers can look back on most difficult cases of this kind.

The Struggle to Survive

DR. W. P. MURRAY (Edinburgh, 12) writes: Your review of *Reproduction and Survival* (June 4, p. 991) contains the words "... the salmon that, after spawning, rapidly ages and dies ..." This may be true of the eel, but it simply is not true of the salmon. When Professor F. J. Browne was in Aberdeen did he never hear of the thousands of "well-mended kelts" that returned to the sea from the Dee?

Obituary

JOHN HENDERSON, M.D., F.R.F.P.S.

Dr. John Henderson died in Glasgow on June 1 at the age of 72. Apart from the first world war, when he served in the R.A.M.C. at home, in Salonika, and in France, his whole medical life had been spent in Glasgow.

After studying at Glasgow University he graduated M.B., Ch.B. in 1898. He proceeded M.D., with commendation, in 1901 and became a Fellow of the Royal Faculty of Physicians and Surgeons of Glasgow in 1910. Already on the junior staff of the Royal Infirmary, he was appointed four years later, at a very early age, physician in charge of wards. These two interests, the Faculty and the Royal Infirmary, were always to take first place in a life that as the years passed become more and more crowded with duties. It was fitting that his services to the Faculty should have been recognized by his election to the presidency in 1937, the year in which he retired from the staff of the Royal Infirmary.

In the wards of the Infirmary there was full scope for Henderson's abilities as a teacher, and there is little doubt that in the years between the wars there was no more popular "chief." He had a natural kindness which endeared him to students, who soon learnt that "Jock" Henderson had an interest in their careers which extended beyond his work as a clinical teacher. Student societies gained his ready support, and even after qualification a student would find himself remembered by some detailed recollection which gave him a sense of personal interest. Contacts with students became even closer when Henderson was appointed assistant to the Muirhead professor of medicine, and then later professor of medicine to St. Mungo's College. In this latter appointment he attracted large numbers to his class. Many American students who attended the Scottish Colleges during the late 'twenties could testify to the soundness of his teaching, and they found something essentially native and salty in this forthright bluff Scot. It was natural that a revision of the students' manual of that time, "Wheeler and Jack," should be placed in his hands. Even the more pedantic student who would affect to frown on this "poited" textbook and declare his preference for some more imposing work as examinations drew near turned to this concise and practical *vade mecum*, which, like its reviser, avoided the frills and stuck to the essentials.

In common with so many others of his generation, Dr. Henderson did not restrict himself to medical affairs. He took a lively interest in the life of the city, and was long connected with one of the ancient Incorporations—the Barbers—of which he was Deacon in 1933, an honour not often conferred on a member of the medical profession and a physician at that. His warm interest in all human activities secured for him an unusually large circle of friends, and his skill at golf and at the bridge table made him a congenial host. A keen churchman, he was, at the time of his death, the senior elder of Lansdowne Church. He was always an active member of the British Medical Association, serving on the Council from 1931 to 1937. He was honorary secretary of the Glasgow and West of Scotland Branch in 1929–32 and president of the Branch in 1934–6. He was also chairman of the Glasgow Division in 1935–6. He gave valuable service to the Medical Planning Commission in 1940, and earlier had been active on a number of central committees.

It no doubt comes naturally to some men to be "givers," and their generosity both in love and in service is well

repaid at life's twilight. John Henderson was one of these men, and his later years were made the happier by the great number of his fellow-citizens, patients, and students who regarded him with an affection often denied to the more austere. Unsparing of himself, it was quite in character that he should have continued teaching medicine to dental students up till almost a week before his death.

He is survived by his widow, a daughter, and a son who is a member of the profession.

Dr. NORMAN GRELLIER, who died at the age of 62 on May 27 after a brief illness, was one of the leading radiologists in Hastings. Born at Epsom in 1886, of Huguenot stock, he was educated at Epsom College and at Charing Cross and the Royal Dental Hospitals, qualifying in dentistry in 1910 and going on to take the conjoint diploma in 1915. He served in the R.A.M.C. in the 1914–18 war, being awarded the Military Cross at the Battle of Passchendaele. During the recent war Dr. Grellier again joined the R.A.M.C., and served as a radiologist from 1941 to the end of the war. On returning to England in 1918 he was appointed dental surgeon to the City of London Police, and was also a demonstrator in dental surgery and later assistant dental surgeon at the Royal Dental Hospital. At Guy's Hospital he later studied medical radiology and electrology, taking the Cambridge diploma in 1924. Then he and his twin brother gave up dentistry and in 1926 settled in St. Leonards, where they had practised as radiologists ever since. Dr. Grellier was honorary radiologist to the Royal East Sussex Hospital, the Hastings Municipal Hospital, and the Eversfield Chest Hospital. Dr. Grellier was chairman of the Hastings Division of the British Medical Association in 1938–9. Up to the time of his death he was president of the East Sussex Medico-Chirurgical Society, and he was a member of the British Institute of Radiology and of the Faculty of Radiology.

He had been master of the Worshipful Company of Tilers and Bricklayers, one of the ancient City companies, a director of the French Hospital, and a fellow of the Huguenot Society of London. He was a freemason and had passed through the chair of the Huguenot Lodge of London. Dr. Grellier's hobbies were model engineering and flying, and he had recently taken up gliding. He and his twin brother, Dr. Bernard Grellier, had never been parted except during war service. They practised together in dentistry and later in radiology, shared the same interests, and had the same outlook in life. Neither was married, and they had always lived together.

Dr. JOHN CURTIS WEBB, who was well known as a radiologist in Cheltenham, died at his home there on May 23 at the age of 80. He was educated at Cheltenham College and Clare College, Cambridge, and was later a student at King's College Hospital, London. He qualified in 1893 and graduated M.B., B.Ch. in 1896. He was house accoucheur at King's College Hospital and subsequently in practice for some years in South Kensington. During the 1914–18 war he served in the R.A.M.C. as a radiologist with the rank of major. He was in charge of the radiological department of No. 7 Stationary Hospital at Boulogne and for his services there he was mentioned in dispatches. He was also awarded the Order of St. John of Jerusalem and the Cruz Vermelha of Portugal. After the war Dr. Curtis Webb was appointed honorary radiologist to the Gloucester Royal Infirmary, and he served in the same capacity at the Children's Hospital and the General and Eye Hospitals at Cheltenham. While in practice in Cheltenham he made several contributions to the literature on electrotherapy, radiology, and radiotherapy. He retired in 1933 but continued to take an active part in the political life of Cheltenham, and during the recent war he did a great deal locally for the Red Cross.

The Services

Air Commodores Abraham B. Briscoe and Christopher Thomas O'Neill, O.B.E., R.A.F., have been appointed Honorary Physicians to the King in succession to Air Vice-Marshal Sir Alan Filmer Rook, K.B.E., C.B., and Thomas McClurkin, R.A.F., respectively, who have vacated the appointments on retirement from the R.A.F.

Medico-Legal

SECRET ADMINISTRATION OF SEDATIVE

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

The Salisbury county court had recently to decide whether a patient has a remedy against a doctor who administers a drug without the patient's consent.¹ Dr. W. J. Drummond sued a woman patient for £17 6s. 6d., professional fees for attendance on her in a Salisbury nursing-home for four months. She counter-claimed for £500 general and £101 4s. special damages.

The patient complained that at the time she was admitted to the home the doctor had said that it would not be necessary to detain her there for more than a few days, but that he had prolonged her stay by causing to be administered to her in her soup and in meat extract secret doses of phenobarbitone, which she had refused to take in the ordinary way. She had found one day an undissolved pellet, and twice every day from then onwards she had hidden the soup and poured it away. She had been nervous and frightened that this would be discovered and the drug put into other food instead. She had lost confidence in doctors and nurses, and as a psychological and physical consequence of the secret administration of the drug her stay had been prolonged for sixteen weeks. She said on cross-examination that she had not packed up and left, because she had had nowhere to go.

Dr. Drummond said in evidence that before she had gone into the nursing-home she had taken phenobarbitone in half-grain (32-mg.) tablets on his prescription. She was a nervous and hysterical patient, and he had prescribed the drug because he had to do something to soothe her. After hearing a broadcast about stolen drugs and their dangers she had refused to take any more. She was beginning to behave in such a childish way and was getting into such a nervous state that he had considered that the simplest way was to ask the matron to give her the drug in her meat extract. In that dose it could not harm a child.

Judge A. H. Armstrong, in a reserved judgment, said the doctor had committed a breach of contract. Where a patient expressly refused to take a particular drug there could not possibly be any implied authority to give it. The doctor could accept the refusal or he could withdraw from the case. He was satisfied that the drug as administered could not have any physical ill effects, but the discovery of the secret administration would be very annoying and distressing to any person. The effect on this patient, who was to the doctor's knowledge unstable emotionally and psychologically, must have been greater than it would have been on a normal person. He gave judgment in favour of the doctor on his claim for fees with costs, but awarded the patient ten guineas on her counter-claim, also with costs.

Presumably to administer a drug without a person's knowledge is a common assault, but if no ill effects were caused the damages could not be more than nominal unless the court desired to make them exemplary. The assault might also constitute a trivial criminal offence. It would not come under the special provisions of the Offences against the Person Act against the administration of a noxious thing.

¹ *Southern Daily Echo*, March 3, 1949.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

A Professorship of Human Ecology in the University is to be established from Oct. 1, with Arthur Leslie Banks, M.D., F.R.C.P., D.P.H., Principal Medical Officer of the Ministry of Health, as the first occupier of the Chair.

Dr. Banks is principal medical officer at the Ministry of Health for the East Anglian, N.W. Metropolitan, and N.E. Metropolitan Hospital Regions, and he has published work on the "National Health Service," "The Care of the Infirm and Long-stay Patient," and "Euthanasia." Qualifying at the Middlesex Hospital in 1926, he graduated with the London degree in 1927 and proceeded M.D. in 1931. He was elected F.R.C.P. in 1948. He is a barrister-at-law of Lincoln's Inn. Cambridge University conferred the honorary degree of M.A. on him in 1946.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 28.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland. Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland. A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

|| Includes puerperal fever for England and Wales, Eire, and Northern Ireland.

EPIDEMIOLOGICAL NOTES

Smallpox

The date of onset in the last case of smallpox notified in England and Wales was May 16. This patient, an unvaccinated close contact, had been admitted to hospital on May 7 as a precaution. After this interval of a month it is assumed that the country is again free from smallpox.

Typhoid Fever

Three cases of typhoid fever, with onset at the end of May, have been notified from Fulham M.B., and the disease is suspected in three other patients. The source of infection is under investigation.

Paratyphoid Fever

Fifteen cases of Vi-phage Type 3A paratyphoid infection have been notified in Tyneside. The vehicle of infection is believed to have been a confection manufactured in Jarrow and consumed about the middle of May. The patients resided in four different sanitary districts. The circumstances suggest that the outbreak was self limiting, and further cases are not expected.

Discussion of Table

In *England and Wales* there were increases in the notifications of measles 1,105, scarlet fever 125, acute pneumonia 44, and dysentery 30. There was a decrease in the incidence of whooping-cough 213.

The largest increases in the notifications of measles were Kent 383, Surrey 137, and Yorkshire West Riding 92, the largest decreases were London 152, Middlesex 77, and Nottinghamshire 62.

A small rise in the incidence of scarlet fever occurred throughout the country, but the only increase of any size was in Yorkshire West Riding 41. The largest change in the notifications of whooping-cough was a decrease of 46 in Lancashire.

There was an increase of 7 in the notifications of diphtheria in Lancashire, the largest returns during the week were Lancashire 25, London 14, and Warwickshire 10. These three areas accounted for one-half of the total notifications of diphtheria.

The increase in the incidence of dysentery was due to an outbreak affecting 30 persons in Yorkshire West Riding, Leeds C.B. The only other large centre of infection was Lancashire 16 (Oldham C.B. 12).

In *Scotland* there were increases in the notifications of measles 117, scarlet fever 52, and dysentery 21. There were decreases in the incidence of whooping cough 38 and acute primary pneumonia 32. Notifications of dysentery came principally from Glasgow 21, Edinburgh 7, and Dundee 6.

In *Eire* increases were reported in the notifications of measles 45 and scarlet fever 19. There was a decrease of 45 in the incidence of whooping-cough.

In *Northern Ireland* only small changes were recorded. Notifications of measles increased in Belfast C.B. 23 and decreased in Co. Down 18. The incidence of whooping cough increased in Belfast C.B. 13, but decreased in most other areas.

Week Ending June 4

Notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,242, whooping-cough 2,178, diphtheria 93, measles 9,773, acute pneumonia 493, cerebrospinal fever 27, acute poliomyelitis 13, dysentery 99, paratyphoid 7, and typhoid 4.

Medical News

Royal Victorian Chain

On the occasion of his Majesty's birthday the King has conferred the Royal Victorian Chain on Sir John Weir in recognition of long and distinguished personal services. The Royal Victorian Chain is not a part of the Royal Victorian Order, of which Sir John Weir was created a Knight Grand Cross. King Edward VII instituted the Chain in 1902 "as a personal decoration for royal personages and a few eminent British subjects." There have been only eighteen holders of the Chain, the last on whom it was bestowed being Dr Fisher, Archbishop of Canterbury.

Peckham Health Centre Appeal

Peckham Health Centre is appealing for funds, and Lord Nuffield, a former president of the centre, has offered £5,000 to be paid when a similar sum has been raised from other subscribers.

Medical Librarians

The medical section of the Library Association, which now has 120 members, held a *conversazione* at the National Institute for Medical Research, Hampstead, on June 10, to enable its members to meet Dr Sanford V. Larkey, president of the (American) Medical Library Association and librarian of the William H. Welch Medical Library, Johns Hopkins University, Dr Henry R. Viets, honorary librarian of the Boston Medical Library and president of the American Association of the History of Medicine, and Miss Mildred Naylor, an officer of the Medical Library Association. Both Dr Larkey and Dr Viets came to Europe to attend the Unesco conference on abstracting and indexing which was held recently in Paris (See p. 1091). Dr Larkey extended to those present a cordial invitation to the next annual meeting of the Medical Library Association, which will be held in Boston in June, 1950. Dr Viets reminded the meeting that the foundation of the association had been due principally to the initiative of William Osler, and that a similar attempt by him in Britain had culminated in the creation in October, 1947, of the medical section of the Library Association. Miss Naylor described her association's scheme for the exchange of duplicate medical literature, nearly 100,000 items were distributed in 1943, compared with 240 when the scheme began nearly fifty years ago.

British Cardiac Society

The thirteenth annual meeting of the British Cardiac Society was held at Newcastle, Co. Down, N. Ireland, on June 2, under the chairmanship of Dr S. Boyd Campbell. At the morning session there was a debate on rheumatic heart disease, with special reference to the pathology of rheumatic carditis and the rheumatic heart in pregnancy. In the afternoon, short communications arranged by the honorary secretary, Dr K. Shurley Smith, included papers on ventricular septal defects, isolated (Fiedler's) myocarditis, non-rheumatic interstitial myocarditis, diagnostic problems in congenital heart disease, and radiology of heart failure due to cardiac intarction, and there was a demonstration of a portable apparatus for the treatment of peripheral arterial disease by intermittent venous occlusion.

Directory of Convalescent Homes

The Convalescent Homes Committee of King Edward's Hospital Fund for London has found it necessary, owing to the very large number of alterations arising from the establishment of the National Health Service, to reprint the Directory of Convalescent Homes in its entirety. All communications concerning the directory should be addressed to the secretary to the committee, Mr R. E. Peers, at 10, Old Jewry, London, E.C.2.

International Health Bulletin

The Health Bureau of the League of Red Cross Societies has just published the first issue of a new quarterly, the *International Health Bulletin*. This new journal will appear in English and French, and a Spanish edition is planned. It is intended to keep the National Red Cross Societies, and particularly their medical members, informed about recent advances in the medical and public health fields. This first number includes articles by Dr Brock Chisholm, General Director of WHO, and by Dr Carl J. Pothof, the medical director of the American Red Cross. There are a number of long abstracts from medical journals, the majority of them relating to problems of special interest to the Red Cross.

Manchester Golfers

The Annual Competition of the Manchester and District Medical Golfers' Association was held at Mere, Cheshire, on May 25. There were 87 competitors. The Challenge Cup was won by Dr T. N. Hart (Bolton), with a net score of 74. The captain's second prize was awarded to Dr K. S. Daber (Bowdon), with a net return of 74. Dr D. C. Racker (Manchester) received the Walter Gold Medal for the best gross score of 76, and the Walter Silver Medal was won by Dr C. W. P. Magahy (Prestwich) for the best gross score of 86 from among those with handicaps of ten and upwards. Club prizes were also won by Dr H. J. Wade (Manchester) and Dr M. L. Thomson (Manchester).

COMING EVENTS

Albert Howard Foundation Lecture

The Albert Howard Foundation Lecture will be delivered, under the auspices of the Albert Howard Foundation of Organic Husbandry, at the Royal Society of Arts, 6, John Adam Street, London, W.C., by Dr A. Guthrie Badenoch on Tuesday, June 21, at 5 p.m., with Professor Wilfrid D. Newcomb in the chair. His subject is "Minerals in Nutrition," and a discussion will follow. The lecture is open to non-members and no tickets are required.

Birmingham Region Consultants

A general meeting of all consultants and specialists in the Birmingham Region will take place on Saturday, June 25, at 2.15 p.m. at Nuffield House, Queen Elizabeth Hospital, Birmingham.

Oxford Graduates' Medical Club

The summer dinner of the Oxford Graduates' Medical Club will be held in Brasenose College, Oxford, on Friday, July 15, when the chair will be taken by Professor A. D. Gardner. Lounge suits will be worn. The accommodation is restricted and no guests can be allowed. All Oxford graduates who are medically qualified are members of the club. Tickets will be issued in return for an application card with 30s., the cost of the dinner including wine, sent to Mr. E. G. Tuckwell, M.Ch., F.R.C.S., 73, Harley Street, London, W.1.

Lecture on Analgesia for Obstetrics

A combined meeting of the North of England Society of Anaesthetists and the Newcastle-upon-Tyne Obstetrical and Gynaecological Society will be held at the Royal Victoria Infirmary, Newcastle-upon-Tyne, on Friday, July 1, at 7.30 p.m., when Dr. Robert A. Hingston, of Baltimore, will deliver a lecture on "Analgesia for Obstetrics."

Cancer Course at Cambridge

A course for general practitioners on the diagnosis and treatment of cancer will be held at Addenbrooke's Hospital, Cambridge, from Monday, July 11, to Friday, July 22. Eleven half-day sessions will consist of lectures and demonstrations. The number attending the course is limited to 30. Details may be obtained from the secretary, the Medical School, the Naval Hut, Downing College, Cambridge.

International Conference on Audiology

The second meeting of the International Conference on Audiology will be held in London immediately before the Fourth International Congress of Otolaryngology. Meetings will be held on Friday, July 15, and Saturday, July 16, at the Royal Society of Medicine, 1, Wimpole Street, London, W.1, at 9.30 a.m. and 2.30 p.m., under the presidency of Professor Gunnar Holmgren, of Stockholm, with Professor H. C. Huizinga, of Gronigen, as secretary, and an international committee, which includes Drs. Norton Canfield and E. P. Fowler, jun. (U.S.A.), Professor E. Luscher (Switzerland), and Mr. C. S. Hallpike (England). The purpose of the conference is to further the investigation, prevention, and alleviation of deafness by means of modern instrumental, educational, and sociological methods. An important part of the programme will be the study of the problems connected with the provision and standardization, upon an international basis, of audiometers and hearing-aids. The provisional programme is: *Friday morning*: Committee meetings. *Friday afternoon*: Papers on various aspects of audiology. *Saturday all day*: A survey of the work in the field of audiology carried out in England during recent years. Papers will be read by otologists, physicists, and by representatives of the Ministries of Health and Education. There will also be a demonstration of instruments developed and sponsored by the Medical Research Council and Ministries of Health and Education, including hearing-aids, group hearing-aids for use in schools for the deaf, pure-tone and other audiometers. The conference is open to all otologists.

Westminster Medical School Centenary

The centenary celebrations of the Westminster Medical School will be held at Church House, Great Smith Street, London, S.W., on Wednesday, July 13, at 3 p.m., when the Earl of Athlone, Chancellor of the University of London, will open the proceedings. Academic dress will be worn.

Education of Maladjusted Children

The Second International Congress for the Education of Maladjusted Children will be held at Amsterdam on July 18-22. The following subjects will be discussed: (a) sensory defectiveness; (b) feeble-mindedness; (c) "difficult" children; (d) one-sided aptitudes. Particulars may be obtained from the Secretariat, Museum Flat, Weteringplantsoen 2 C., Amsterdam, Holland.

Exhibition of Medical Photography

The Medical Group of the Royal Photographic Society is holding an exhibition of medical photography at the society's house, 16, Princes Gate, London, S.W., from July 4 to 16. Sir Cecil Wakeley will formally open the exhibition at 6.30 p.m. on July 4. It will be open from 10 a.m. to 5 p.m. and admission is free.

SOCIETIES AND LECTURES**Saturday**

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.—At Queen Mary's Hospital for Children, Carshalton Beeches, Surrey, June 18, 2.30 p.m., clinical meeting.

Monday

EDINBURGH UNIVERSITY.—At Physiology Lecture Theatre, University New Buildings, Teviot Place Edinburgh, June 20, 5 p.m., "The Early Days of the Edinburgh Medical School," by Dr. Douglas Guthrie.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., June 20, 5 p.m., "Injuries of the Bladder, Foreign Bodies in the Bladder," by Mr. J. G. Sandrey.

PHARMACEUTICAL SOCIETY (ROCHDALE AND DISTRICT BRANCH).—At "The Carlton," Great George Street, Rochdale, June 20, 8 p.m., "The New Formulary," by Mr. A. G. Fishburn, Ph.C., F.R.I.C. Members of the Rochdale Division of the B.M.A. are invited to attend the meeting.

Tuesday

ALBERT HOWARD FOUNDATION OF ORGANIC HUSBANDRY.—At Royal Society of Arts, 6, John Adam Street, London, W.C., June 21, 5 p.m., "Minerals in Nutrition," Albert Howard Foundation Lecture by Dr. A. Guthrie Badenoch. A discussion will follow.

CHADWICK TRUST.—At 26, Portland Place, London, W., June 21, 2.30 p.m., "Evolution of Industrial Work for Women and Young Persons and its Effect on the National Health," Chadwick Public Lecture by Dr. Sibyl Horner.

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At Anatomy Lecture Theatre, University New Buildings, June 21, 5 p.m., "Pneumoconiosis," by Dr. E. R. Boland.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—June 21, 5 p.m., "Varicose Eczema, Ulceration, Etc.," by Mr. A. K. Monro.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., June 21, (1) 11 a.m., "Treatment of Gonorrhoea and its Complications," by Dr. A. H. Harkness; (2) 5 p.m., "Calculus Disease of the Bladder and Urethra," by Mr. F. R. Kilpatrick.

Wednesday

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., June 22, (1) 11 a.m., "Ocular Manifestations of V.D.," by Dr. A. H. Harkness; (2) 5 p.m., "Marion's Disease (Bladder Neck Obstruction) and Vesical Diverticula," by Mr. W. K. Irwin.

Thursday

GUY'S HOSPITAL MEDICAL SCHOOL, London Bridge, S.E.—June 23, 5 p.m., "Thomas Addison—Pioneer of Endocrinology," Addison Lecture by Sir Henry Dale, O.M., F.R.S.

INSTITUTE OF UROLOGY.—At St. Paul's Hospital, Endell Street, London, W.C., June 23, (1) 11 a.m., "Chancroid," by Dr. W. N. Mascall; (2) 5 p.m., "The Aetiology, Pathology, and Symptoms of Benign Enlargement of the Prostate, with Indications for Treatment," by Mr. F. J. F. Barrington.

LONDON: UNIVERSITY COLLEGE.—At Physiology Theatre, Gower Street, W.C., June 23, 4.45 p.m., "Some Aspects of Nitrogen Metabolism in the Mammal," by Dr. J. S. Bach.

MEDICO-LEGAL SOCIETY.—At 26, Portland Place, London, W., June 23, 8 p.m., (1) annual general meeting; (2) "The Legal and Economic Status of Women," by Mrs. Florence Earengay, J.P., B.A.

NORTH-EAST METROPOLITAN REGIONAL TUBERCULOSIS SOCIETY.—At "The Haris" Sanatorium, Snakes Lane, Woodford Green, Essex, June 23, 2.30 p.m., "The Assessment of Collapse Therapy in Pulmonary Tuberculosis," by Dr. Philip Ellman.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—June 23, 4.30 p.m., "Psychiatry," lecture-demonstration by Dr. D. Curran.

Friday

CAMBRIDGE MEDICAL SOCIETY.—At Addenbrooke's Hospital, Cambridge, June 24, 2.30 p.m., "Some Problems in Connexion with Injuries to the Knee," by Mr. T. J. Fairbank.

ROYAL SANITARY INSTITUTE.—At Town Hall, West Hartlepool, June 24, 10 a.m., Discussions: "Post-war Legislation and its Effect on Local Health Authorities," to be opened by David T. Jones, M.P.; "Neighbourhood Planning," to be opened by J. Stanley Miles, A.M.I.C.E.

WESTMINSTER HOSPITAL SCHOOL OF MEDICINE, Meyerstein Lecture Theatre, Horseferry Road, London, S.W.—June 24, 5.30 p.m., clinico-pathological meeting, "Haemolytic Anaemia," by Drs. J. G. Humble and R. H. Trinick.

BIRTHS, MARRIAGES, AND DEATHS**BIRTHS**

Farey.—On June 6, 1949, to Mary (née Maish, M.B., B.S.), wife of A. Leonard Farey, a daughter.

Fleming.—On May 22, 1949, at the General Hospital, Newcastle-upon-Tyne, to Margaret (née Primrose Walker), M.A., M.B., Ch.B., and John Mansell Fleming, 25, Roseworth Avenue, Gosforth, a son.

Rutter.—On June 7, 1949, to Norrie, wife of Timothy E. Rutter, F.R.C.S.Ed., of Penwithen, Gerrans, Portscatho, Cornwall, a brother for Timothy and Michael.

Uhma.—On June 5, 1949, at Hammersmith Hospital, London, W., to Halina (née Dabrowska), wife of Dr. C. Uhma, a daughter—Joanna.

DEATHS

Anderson.—On June 5, 1949, at 35, Richmond Hill Road, Edgbaston, Birmingham, Robert Anderson, M.D., late of Erdington, aged 82.

Cowan.—On June 9, 1949, at 15, West Parade, Lincoln, Alistair Forbes Cowan, F.R.C.S.Ed., formerly of Edinburgh, aged 62.

Easterbrook.—On June 5, 1949, at Murrayfield Private Hotel, Edinburgh, Charles Cromhall Easterbrook, M.D., F.R.C.P.Ed., in his 83rd year.

Ferrier.—On June 8, 1949, at 22, Moor Road, Swanage, Dorset, David Hynd Ferrier, M.D., late of Luton, Beds, aged 74.

Gibson.—On June 4, 1949, at "The Gables," New Brighton Road, Emsworth, Hants, Henry Wilkes Gibson, M.B., in his 82nd year.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Lupus Erythematosus

Q.—Is there any evidence that lupus erythematosus has a metabolic origin, as, according to Canadian trials, vitamin E in large doses has influenced the process favourably? Has this finding been confirmed? Also, has the vitamin-B group been tried, and, if so, with what success? Finally, in the dietary management of this complaint has it been noticed that any type of food is of special value or harm?

A.—There is some evidence that acute lupus erythematosus, which is a serious systemic disease, is a separate entity from chronic fixed lupus erythematosus, though it is a fact that on occasion an acute phase is superimposed upon the chronic disease. The cause of lupus erythematosus remains obscure. The very occasional finding of an organism in the blood stream in acute lupus erythematosus, and the occasional resolution of the chronic type following treatment of a focus of infection, have left the impression that the disease is commonly infective or toxic, but the evidence is not very convincing. The condition would seem to be an essential disease of the blood vascular system with an unusual pathology. Vitamin E has been advocated in North America, more particularly for the acute cases, but success has not attended its use in this country. The dosage recommended is 300 mg daily of mixed tocopherols, a preparation containing mixed tocopherols in 30-mg capsules is obtainable.

Foods appear to play no part in this disease, and vitamin-B therapy in ordinary dosage has not proved of any particular value.

Inhalation of Propylene Glycol

Q.—I am employing propylene glycol as a solvent for sodium penicillin salt, and am using the solution, in aerosol form, for the mass treatment of chronic chest diseases in children attending an open air day school. The children are exposed to the aerosol for two hours every school day, and it is intended to continue this treatment for six months to a year or more in each case. Is the prolonged inhalation of propylene glycol vapour likely to have any untoward effects?

A.—Robertson and his colleagues (*J Pharmacol*, 1947, 91, 52) exposed rats and monkeys to continuous high concentrations of propylene glycol vapour for periods of 12 to 18 months. The general condition of the animals, their growth rates, blood counts, and the results of urine examination and kidney function tests did not differ essentially from control groups, nor were any macroscopical or microscopical changes noted at necropsy. These results, together with the absence of any reported ill effects in patients exposed to the vapour, make it unlikely that the regimen suggested will cause any trouble. The children should, of course, be kept under close medical supervision.

Penicillin-Sulphathiazole Snuff

Q.—The use of penicillin and sulphathiazole powder as a snuff has proved effective in aborting colds and in preventing the long period of "snuffles" which so often follows a cold. In using the preparation in this way, is there any danger of producing resistant organisms?

A.—The most common secondary bacterial invader after the common cold (which may be presumed to be due to a virus) is the pneumococcus. It seems possible that the pneumococcus and other organisms play some part in the persistent discharge or "snuffles" which is a common sequel to the cold. Penicillin-sulphathiazole snuff is usually given in a high enough concentration to eliminate organisms, and therefore the risk of breeding resistant strains would be very small. The organism which most readily develops penicillin-resistance is the staphylococcus, and this of course is present in the anterior nares of 40 to 50% of the population. It is doubtful if the staphylococcus plays

much part in catarrhal infections of the upper respiratory tract, but frequent applications of penicillin to the nose might lead to an increase in the proportion of penicillin-resistant staphylococci, and, since the nose is the natural reservoir of the staphylococcus, this might in turn lead to an increase in the incidence of staphylococcal infections with penicillin resistant strains.

Protecting Skin from Mineral Oils

Q.—Would you recommend a suitable preparation for application to the hands and forearms before starting work to ensure protection from dermatitis in petrol-oil and diesel-oil workers?

A.—There is no preparation which, by its application to the skin before work, will "ensure protection from dermatitis." Barrier preparations are only one of the several measures needed for protection against occupational dermatitis, and, where the skin hazard is mineral oil, barrier preparations are not as useful as suitable skin cleansers. Many cleansers are effective in removing oil from the skin, but some of these will also, particularly with prolonged use, remove the skin fat. A neutral sulphonated castor oil (98%) with a wetting agent (2%) is generally recommended to cleanse the skin of mineral oil.

Sterilizing Gum-elastic Catheters

Q.—Can you recommend an efficient method, suitable for general practice, of sterilizing and transporting gum-elastic catheters?

A.—The most convenient way of sterilizing and transporting gum-elastic catheters is by the formalin vapour method. A glass or metal tube with a rubber stopper that is hollow, so that formalin tablets can be inserted into it, is obtainable at most instrument-makers. There is a disadvantage, however, in retaining catheters in such a receptacle for too long: moisture tends to collect on the inner surface, as well as some fine dust from the tablets. The catheter should therefore be inserted in the receptacle only a few hours before transport.

Painful Breasts due to Stilboestrol

Q.—A patient suffering from pruritus has found that an ointment containing stilboestrol gave great relief, but after using it for some months the breasts became painful and tender. She is now using the ointment without the stilboestrol. Although it is four months since she used the original preparation, the breasts are still sore, but not swollen or enlarged. Can relief be obtained in this case, and is there any reason to fear that the condition will become malignant?

A.—Stilboestrol even in small amounts is readily absorbed through the skin and could give rise to painful and tender breasts. These effects, however, are not likely to persist for four months after discontinuing treatment, unless some other oestrogen was substituted for the stilboestrol. It may be that the occurrence of symptoms produced a natural anxiety over the possibility of the development of cancer, and the persistence of discomfort is now the result of over anxiety alone. There is no reason to believe that the present treatment or the continued discomfort implies an increased risk of carcinoma, and if a competent medical attendant has failed to find clinical evidence of organic disease probably all that is necessary is a well fitting brassiere and, above all, a comfortable frame of mind.

Sal Volatile and Eau-de-Cologne

Q.—(a) Would you indicate the therapeutic value, if any, of sal volatile? (b) A sufferer from migraine with possible chronic sinusitis, gets partial or complete relief from inhalation of eau-de-Cologne. Can this be attributed to some intracerebral action, or must it relieve only by action on the nose and sinuses?

A.—(a) Spirit of sal volatile contains ammonium carbonate and strong solution of ammonia. When smelt, so that it irritates the mucous membrane of the nose, sensory impulses travel to the medullary centres, stimulating respiration and the vasomotor centre. A discharge of sympathetic impulses quickens the heart and raises the blood pressure.

(b) It is very unlikely that the effect of eau-de-Cologne is due to an intracerebral action, but it is not impossible. Eau-de-Cologne is composed mostly of alcohol with a number of

volatile oils, and it may be that when it is inhaled a certain concentration of alcohol and these oils is formed in the blood and that this affects the blood-flow through the head, so relieving the migraine. It is difficult to understand what action there could be on the nose and sinuses which would take away an attack.

Treatment of Chronic Brucellosis

Q.—In the answer to a question on persistent symptoms after brucella infection (Feb. 5, 1949, p. 254) you suggest simultaneous administration of streptomycin and sulphadiazine. Can you give me references for details of dosage?

A.—The following papers contain details of the dosage of streptomycin and sulphadiazine used in the treatment of chronic brucellosis: Eisle and McCollough, *J. Amer. med. Ass.*, 1947, 135, 1053; Pulaski and Amspacher, *New Engl. J. Med.*, 1947, 237, 419; Spink, *Ann. intern. Med.*, 1948, 29, 238; Scowen and Garrod, *British Medical Journal*, 1948, 2, 1099.

It seems likely that aureomycin will displace the combination of streptomycin and sulphadiazine in the treatment of this infection, and details may be found in Bryer, Schoenbach, Chandler, Bliss, and Long (*J. Amer. med. Ass.*, 1948, 138, 117) and Spink, Hall, Schaffer, and Braude (*ibid.*, 138, 1145). The immediate results of treatment with aureomycin in a case of *Br. abortus* infection were also recorded in the *Journal* of June 11 at p. 1037.

Subconjunctival Haemorrhage in a Baby

Q.—At birth a baby had a bilateral symmetrical haemorrhage, presumably subconjunctival, encircling both corneae. Now, a month later, the condition is clearing in the left eye, but little if any change is seen in the right eye. Is any treatment indicated? Can the mother be reassured that the condition is only temporary, and that in course of time it will resolve completely?

A.—The diagnosis of subconjunctival haemorrhage is probably correct. Its appearance in both eyes and persistence for a month in one eye are rather unusual. The prognosis depends on the diagnosis in this case, and it is impossible to be dogmatic without actually seeing the baby. On the whole, it is probably safe to assume that the condition is temporary and will resolve completely.

Effects of Chemical Contraceptives

Q.—Have any investigations been undertaken to show the part played by chemical contraceptives in the causation of abortion and foetal abnormalities? Surely an injured spermatozoon must occasionally fertilize an ovum and give rise to an abortion or to the birth of a deformed infant?

A.—The possibility that chemical contraceptives may have such an effect has been considered and discussed for many years, but so far there is no reliable evidence to support the theory that this risk exists. As the first effect of spermicidal agents is on the motility of spermatozoa, it seems unlikely that a spermatozoon which is damaged would ever reach the ovum. Moreover, it has not yet been established that a high proportion of abnormally developed spermatozoa in the semen is related to the incidence of abortion and foetal malformation, although many writers have suggested it, and it seems a reasonable possibility.

Cephalin-Cholesterol Flocculation Test

Q.—Would you kindly let me know details of the procedure for extracting cephalin from dried sheep's brain? Would you also tell me how to carry out the cephalin-cholesterol flocculation test?

A.—The preparation of cephalin from sheep's brain and its use for the cephalin-cholesterol flocculation test have been described by Hanger (*J. clin. Invest.*, 1939, 28, 261).

Preparation of Cephalin.—Sheep brains are dehydrated by three extractions with acetone and the dry tissue powder is three times extracted with ether (free from peroxides). The ether extracts are concentrated *in vacuo* and the crude cephalin is precipitated by the addition of four volumes of absolute alcohol. The resulting precipitate is dissolved in the minimum amount of ether, and the accompanying cerebroside impurities are precipitated by chilling and removed by centrifugation. The supernatant ether solution is again precipitated with four volumes of absolute alcohol, chilled, and the precipitate is filtered, washed with alcohol and acetone, and

desiccated. The cephalin preparation is a brown powdery material containing traces of other lipids. These, however, do not take part in the reaction.

Technique for Flocculation Test.—A stock solution is prepared by dissolving 100 mg. of sheep-brain cephalin and 300 mg. of cholesterol in 8 ml. of ether. This solution can be kept many months without deterioration in a well-stoppered container. An emulsion of a cephalin-cholesterol complex may be prepared by adding (slowly and with stirring) 1 ml. of the stock ether solution to 35 ml. of freshly distilled water warmed to 65° to 70° C. and then heating slowly to boiling. The mixture is allowed to simmer until the final volume is reduced to 30 ml. During the heating all coarse granular clumps are dispersed to a stable, milky, translucent emulsion and all traces of ether are driven off. After allowing it to cool to room temperature the preparation is ready for testing, which consists in adding 1 ml. of the emulsion to a test tube (preferably a centrifuge tube) containing 0.2 ml. of the patient's serum diluted with 4 ml. of normal (0.85%) saline. After being thoroughly shaken and stoppered with cotton, the tube is allowed to stand undisturbed at room temperature. At the end of 24 and 48 hours the amount of flocculation and precipitation that has taken place is noted. With normal human sera the emulsion remains as a stable homogeneous suspension, but with sera from patients with diffuse hepatitis the lipid material tends to flocculate and precipitate to the bottom of the tube. A reaction recorded as + + + + indicates a complete precipitation, leaving the supernatant liquid water-clear. Gradations of the reaction between negative and + + + + are designated + or ++, or + + +. No test should be regarded as negative until 48 hours have elapsed without flocculation having occurred.

NOTES AND COMMENTS

Safe Dose of Acetylsalicylic Acid.—Dr. A. PINEY (London, W.) writes: In "Any Questions?" (April 23, p. 735) there is rather too sweeping an indictment of prolonged treatment with acetylsalicylic acid, inasmuch as menaphthone is mentioned as the only available method of counteracting the effect of a large dose on the prothrombin level. Szucs has shown (and his observations have now been extensively confirmed) that the addition of calcium succinate greatly reduces (or abolishes) this effect (*Ohio St. med. J.*, 1947, 43, 1035). Thus 120 gr. (8 g.) of acetylsalicylic acid for ten days causes a fall of about 20% in blood prothrombin, and the addition of 90 gr. (6 g.) of calcium succinate to the daily dose prevents the fall. For prolonged treatment such a mixture is obviously more satisfactory than is preliminary administration of menaphthone.

Grading of Catheters.—Mr. J. A. CARR (Ashton-on-Ribble, Preston) writes: Your answer ("Any Questions?" May 14, p. 879) on the grading of catheters properly advocates the use of the Charrière scale, and draws attention to the failings of the characteristically English scale which . . . "follows no rule, but its numbers are generally about two less than the American" (Keyes, E. L., and Ferguson, R. S., *Urology*, 1936). A difficulty arises in applying catheter scales, which as you point out are of diameter, to instruments which are not circular in cross section. These instruments should be given the grade of the catheter which has the same circumference, for that is what the urethral mucosa has to accommodate. Some time ago I devised a measuring strip for the purpose of checking the grading of urethral instruments. In the illustration there is an accurate reproduction of the measuring strip, and a sketch showing its method of use. The scale is drawn by making the distance from the point of the arrow to the graduations (at the opposite edge of the strip) equal to the circumference of a catheter of the same grading—e.g., a distance of 3.14 cm. in the case of 30F.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JUNE 18 1949

THE SECRETARY REPORTS

MINISTRY'S TERMS FOR HOSPITAL STAFFS

The terms and conditions of service of hospital medical and dental staff, and the Ministry's explanatory memorandum (*Supplement*, June 11, p. 314), represent the limit to which the Joint Committee has been able to secure concessions by negotiation.

During the next few weeks consultants and specialists will have an opportunity of discussing the terms at meetings. A number of the more important issues are discussed below, including a comparison between the representations made by the Joint Committee and the reactions of the Ministry as embodied in the final terms of service.

Senior Hospital Medical Officers

The Joint Committee has expressed the view that no proper distinction can be drawn between junior specialists and full specialists. A practitioner is either a specialist or not, and it is a matter for regret that the Ministry should have suggested to Review Committees that so-called junior specialists should be graded as senior hospital medical officers. The Joint Committee therefore asked that a system of appeal should be established by which a practitioner not satisfied with his grading can secure a review of his assessment by a committee other than the one which made the first assessment. Further, the Joint Committee sought an assurance that no specialist subsequently appointed would be graded as a senior hospital medical officer and that no additional appointments would be made to this grade except in such limited field as may be agreed between the Ministry and the Joint Committee.

The Ministry proposes that senior practitioners performing clinical duties who are not of consultant status and are not registrars be appointed to the senior hospital medical officer grade, but that the term need not be adopted as a title describing individual officers holding the posts in this grade. Boards are free to use whatever terminology is preferred—e.g., an anaesthetist holding a post in the senior hospital medical officer grade might be given the title of "anaesthetist"—a specialist in the same field being called a "consultant anaesthetist."

On the question of appeal, the Ministry has agreed that aggrieved practitioners shall have a right of appeal to the Review Committee, the committee being enlarged for the purpose by the addition of two members—one nominated by the appropriate Royal College, and one drawn from the Review Committee of an adjoining hospital region.

Security of Tenure

The Joint Committee has sought to secure adequate safeguards for consultants and specialists holding appointments in the hospital service and has put forward the following proposals on security of tenure.

Where the appropriate committee of a board proposes to recommend to the board the termination of a specialist's contract, the board, before considering the matter, should refer it to a central professional committee for examination, the board being directed thereafter to proceed or not to proceed with the termination of the contract of the practitioner in question in the light of the findings of the central professional committee.

The central professional committee should consist of the Chief Medical Officer of the Ministry as chairman, two registered medical practitioners selected by him, and three specialists nominated *ad hoc* by the Joint Committee. The chairman should not have a casting vote.

An aggrieved specialist should have the right to appear personally before the central professional committee, and to have the assistance of a professional colleague if he so desires.

The Joint Committee considers that the following provision should be included in Paragraph 14 and embodied in the contract as part of the terms of service:

In conformity with the assurance given by the Minister of Health that existing hospital staffs would be taken over at the appointed day, and that after the review of the specialist services boards will offer new appointments to their staffs either in their existing or in other hospitals, security of tenure of the number of sessions of specialists rendering part-time service shall be maintained. Where the number of sessions performed by a specialist at any one hospital is substantially curtailed through no fault of the specialist, the regional hospital board (or board of governors either directly or in conjunction with the regional hospital board) shall be responsible for providing alternative sessions in another hospital in the region. Where the board is unable to do so the Minister shall assume responsibility for offering a suitable alternative post under another board. The same procedure shall apply to new entrants.

Medical superintendents and senior hospital medical officers should have the same security of tenure in their appointments as specialists.

The Ministry proposals do not go as far as those put forward above. In effect they provide that, where a consultant considers that his appointment has been unfairly terminated by a board, he shall be entitled to send a full statement of the facts to the Minister, who will obtain the written views of the board concerned and put the case before a professional committee (consisting of representatives of the Ministry and of the profession, under the chairmanship of the Chief Medical Officer) for its advice. The committee will have discretion to interview both parties if it thinks fit. In the light of its advice the Minister may confirm the termination of services or direct reinstatement, or arrange some third solution agreeable to the parties concerned, such as re-employment in a different post.

Although it is envisaged that this procedure will be completed before the board's decision is put into effect, the machinery of dismissal with its implied stigma is put into operation before the consultant has had an opportunity of stating his case to the appeal body.

The terms include a paragraph to the effect that, where a change of organization in the hospital and specialist services involves displacement or serious disturbance of a part-time consultant's services, the board has a moral obligation to "render the greatest possible assistance" to the consultant to obtain comparable work in another hospital.

Medical Superintendents

The Joint Committee considers that rates of remuneration for medical superintendents should not be prejudiced by considerations of policy on what should be the appropriate form of hospital administration in the future. Therefore the remuneration attached to hospital appointments in the field of medical administration should be appropriate to the status and qualifications of a medical practitioner.

The Joint Committee accordingly recommended:

(i) that where a medical superintendent is classified as a specialist he should be remunerated as a specialist whatever the proportion of time spent on administration;

(ii) that a medical superintendent not classified as a specialist should be on a salary scale of £1,500 to £2,500, according to the size and character of the hospital and the duties involved.

The Ministry proposes that a medical superintendent be paid a salary consisting of a fraction of the whole salary of a consultant or senior hospital medical officer according to his grading in respect of the time given to clinical work and a fraction of the appropriate rate for hospital administrative staff for the time given to administrative work.

The Ministry has, however, conceded the point that when a whole-time officer is engaged almost wholly on clinical work, and gives only a small proportion of time to administrative duties, his appropriate clinical remuneration shall not be affected.

Part-time Consultant Appointments

In general, the Ministry has accepted the Joint Committee's proposals for calculating the remuneration of part-time specialists, and in the explanatory memorandum points out that boards are expected to make a pre-contract assessment of the duties attached to the post in terms of the time which should be taken by an average practitioner to perform the duties. There will therefore be no need for consultants to "clock in and out."

It is recognized that consultants engaged in teaching duties will require more time in undertaking a session than a non-teacher, and this factor will be taken into account in assessing the number of notional half-days. Arrangements will be made for the pre-contract assessment to be reviewed from time to time.

Part-time Registrars

Part-time appointments in the registrar grades will be calculated on a number of notional half-days.

This is a new point which did not appear in the provisional terms.

Maximum Remuneration for Part-time Appointments

It is proposed that the maximum remuneration for part-time specialists shall be $\frac{9}{11}$ of the whole-time remuneration appropriate to the officer concerned and for registrars $\frac{9}{11}$ of the whole-time salary.

Exceptional Consultations

The Joint Committee has urged that payments for exceptional consultations should be on a sessional basis at the rate appropriate to the seniority of the specialist concerned—i.e., at the same rate as for the specialists' contractual duties. But the Ministry has adhered to its original proposal that payment should be at the rate of 5 guineas a visit, any operative work being included.

Domiciliary Consultations

The Ministry has agreed to the Joint Committee's suggestion that the title "domiciliary visit" should be changed to "domiciliary consultation." This change is important because it makes a distinction between consultations at the request of a general practitioner and domiciliary visits for the purpose of routine treatment such as are carried out by tuberculosis officers.

The Joint Committee considered that whole-time specialists should not in principle undertake domiciliary consultations except (a) where there is no part-time specialist available or (b) where the character of the specialty is such as to necessitate the attendance of a whole-time specialist. The Ministry proposes that whole-time officers should undertake domiciliary work but that their liability in this field should be clearly defined and limited and should not be additional to normal whole-time commitments but part of them. Whole-time specialists will not receive additional payments for domiciliary consultations. The terms of service provide for domiciliary consultations to be undertaken by senior hospital medical officers.

The Ministry has not given effect to the Joint Committee's proposal for an increase in the travelling and subsistence allowances or for the removal of the ceiling of remuneration for domiciliary consultations, but specialists undertaking this work are given the option of having the maximum calculated as 200 guineas in any one quarter or 800 guineas in any one year.

Clinical Consultants Teaching Medical Students

The Joint Committee has pressed for a national agreement for the payment of clinical teaching to be negotiated and promulgated before contracts are offered. The Ministry proposes that whole-time clinical consultants engaged in teaching shall hold honorary unpaid appointments with the appropriate hospital board and shall receive from the board appropriate expenses for hospital work. They will also be eligible for distinction awards. Part-time specialists who teach will be remunerated by hospital boards (including distinction awards and expenses) in addition to any remuneration they may receive from the university or teaching school for teaching duties.

Clinical Consultants Engaged in Teaching (Document, paragraph 9)

The University Grants Committee in making grants to universities will have regard to the following salary rates (operating from April 1, 1949) for holders of whole-time clinical posts in medical and dental schools:

Professors: Within the range of £2,250 to £2,750.

Lecturers: £600 to a maximum within the range of £1,500 to £2,000 (or £2,500 for posts carrying special responsibility).

Readers: Within the range of £1,500 to £2,000 (or £2,500 for posts carrying special responsibility).

Boards will pay no remuneration whatsoever to holders of these posts or to clinical professors, heads of university departments, etc., who devote a large part of their time to university work. (In cases of doubt the university or school should be asked whether they regard the clinical teacher as coming under paragraph 9 (1) or 9 (2) of the Terms of Service.) These officers will hold honorary unpaid appointments with the board and will thereby be eligible for distinction awards. Where an award is granted, the board will pay over to the university or medical or dental school the value of the award (or, in the case of holders of part-time teaching appointments, the appropriate proportion of the value) so that the university or school may include this in the remuneration they pay to the teachers. This remuneration is not superannuable under the National Health Service Superannuation Scheme.

The Joint Committee considers these proposals to be inadequate, and have urged that discussions on a national level should be held as soon as possible.

Determination of Salaries Payable from July 5, 1948

The salaries of consultants, payable from July 5, 1948, will be the salary which the officer would have been receiving on that date had the proposed system of remuneration been in operation since the date on which he first accepted a hospital staff appointment with full clinical responsibility.

It is stated that there must have been no break of service, but the Ministry has agreed with the Joint Committee's contention that war service or national service on call-up will not constitute a break for this purpose.

In the case of senior hospital medical officers, boards have discretion to decide at which point in the salary scale existing staff should start provided that the starting salary shall in no case be higher than that which the officer would receive were his position on the scale determined by age alone. Officers who were transferred under Section 68 of the National Health Service Act and who, immediately before July 5, 1948, were receiving salaries better than those now introduced will be entitled to receive their previous salary scale and conditions of service on a personal basis for so long as they remain in the same appointment, or another appointment of the same or greater responsibility, as the one they held at the appointed day.

Car Allowance

The Joint Committee made a number of recommendations for improvement of the travelling allowances. These recommendations are not reflected in the final terms.

Are the Terms Acceptable?

Only the more important points in the final terms have been referred to above, and the comparisons drawn between the recommendations of the Joint Committee and the Ministry's final terms are not a substitute for the two documents published last week. The task before consultants and specialists is clear. It is for each individually to decide whether the terms are sufficiently acceptable to justify consultants and specialists signing the permanent contracts offered to them. The Joint Committee is seeking the views of its constituent bodies on this issue and will meet on July 5 to decide the character of the advice to be given to the profession. The Central Consultants and Specialists Committee, before expressing its view, will have before it the opinions of the various regional committees. In the meantime, specialists are again advised not to sign permanent contracts until the Central Committee has met and expressed its view.

A NON-MERCURIAL FUNGICIDE FOR TINEA PEDIS

The summer season brings an increase in the number of cases of epidermophytoses of the feet (athlete's foot) and similar mycotic infections of the axillæ and perineal regions. MYCIL is a non-mercurial fungicide, evolved in the laboratories of The British Drug Houses Ltd., which is strongly inhibitive to the growth of the causative organisms of tinea pedis.

MYCIL is issued both as an ointment and as a powder. Clinical results confirm the effectiveness of the combined application.

MYCIL Dusting Powder is particularly useful as a preventive against re-infection when clinical cure has been obtained.

LAWS OF MEDICINE

Bell's Law

*"The anterior roots of
the spinal nerves are
motor, and the posterior
roots are sensory"*

This illustration, drawn by Bell himself, is taken from his book on the study of nerves, published in 1816. SIR CHARLES BELL (1774-1842) was equally eminent as a surgeon and an anatomist. He was Surgeon to the Middlesex Hospital from 1815 until 1835, when he was appointed to the Chair of Surgery in Edinburgh.

TO BELL and other great pioneers of the nineteenth century, we owe the beginning of modern knowledge of anatomy and physiology. More recent and even more spectacular is the advance attained in therapeutics since the introduction of synthetic compounds.

In this and every other branch of drug manufacture, the Boots organisation is constantly active to meet the needs of modern therapy. Behind its great resources for research and production there is a long tradition of service to the medical profession.

P-4

for swift **A** saturation

Intolerance, or prejudice against fat-rich foods must ultimately result in a marked deficiency of vitamin A. Too often this deficiency goes undetected until such symptoms as dry, scaly eruptions, poor dark adaptation or general susceptibility to infection bring the sufferer to your surgery. Rapid vitamin A saturation can normally be achieved by giving 'Prepalin' orally in capsule form. In exceptional cases, however, 'Prepalin' may be given by intramuscular injection.

Even infants tolerate 'Prepalin' by mouth perfectly well, and 'Prepalin' Liquid given regularly in the early years is a wise precaution against the disorders of growth that characterise avitaminosis A.

PREPALIN

CAPSULES: Each capsule contains 24,000 i.u. of vitamin A.
In bottles of 25 and tins of 100.

LIQUID: 72,000 i.u. per cc. In 8 cc. bottles.

1 cc. AMPOULES: 100,000 i.u. 6 x 1 cc. 12 x 1 cc.

GLAXO LABORATORIES LTD., GREENFORD, MIDDX. BYRON 3434

TEMPORIS ARS MEDICINA FERE EST (OVID)

The art of medicine is generally a question of time. With the peptic ulcer patient, as is well known, the rate of healing is determined by the ulcer's freedom from irritation. By rapidly buffering excess acid and at the same time avoiding acid rebound, 'ALUDROX,' a suspension of 5.6% colloidal aluminium hydroxide in gel form, ensures rest for the ulcer. Pain is relieved and time taken for healing reduced to a minimum.

National Health Service

FACTORY MEDICAL SERVICES

Factory inspectors have recently investigated the medical services in different kinds of factories in Britain for the Ministry of Labour. The inquiry was carried out on the suggestion of a subcommittee of the Industrial Health Advisory Committee.

The inquiry shows that out of 243,769 factories in Britain 4,499 have definite arrangements for some kind of medical services other than statutory examinations of young persons. General medical supervision is provided in 2,525 factories, supervision of first-aid and ambulance-room services in 2,511, and in 2,274 factories particular groups of workers—e.g., those subject to special health risks—are given a periodical medical examination.

A periodical medical examination of all workers is given at the factory in 229 instances, and at the doctor's surgery in 18. New entrants and applicants are examined in 1,558 factories and at the doctor's surgery in 225. At 1,159 factories there is provision at the factory for examining workers returning after illness, and at 141 at the doctor's surgery.

Group Medical Services

The inquiry shows that there appear to be only three schemes of group medical services for small independent factories as distinct from factories run by large or closely associated concerns. These are at the trading estates at Slough, Bridgend, and Hillington. The Slough scheme covers 113 factories, of which 33 employ fewer than 26 workers; the Bridgend scheme covers 39 factories, of which 15 employ fewer than 26 workers; and the Hillington scheme covers 126 factories, of which 69 employ fewer than 26 workers.

Extra Supervision

Inspectors were asked whether in their districts there are any industries which predominantly stand out as having factories with arrangements for medical supervision beyond legally compulsory medical examinations. Most of the replies were negative, but it seems that the following did fall into that category: dockyards and other factories occupied by the Admiralty, Royal Ordnance factories, the aircraft industry, shipbuilding, iron and steel manufacture, the metal tube industry, the chemical industry (particularly at factories occupied by Imperial Chemical Industries), the tobacco and cigarette industry, electric cable and large electrical manufacturing undertakings, and cotton spinning.

Factory Doctors

Whole-time service is given by 53 doctors who hold appointments as "appointed factory doctors," and 586 who are not "appointed factory doctors." Of appointed factory doctors doing part-time work, 94 do a substantial amount (more than 12 hours a week on the average), 245 between three and 12 hours a week, and 1,397 three hours a week or less; of those not appointed factory doctors, the numbers are respectively 111, 406, and 584.

REVIEW COMMITTEES

Enlarged to Hear Appeals

When review committees of regional boards hear appeals from practitioners who disagree with their grading they will be enlarged by the addition of two members—one nominated by the appropriate Royal College according to the specialty of the practitioner, and one drawn from the review committee of an adjoining hospital region. This decision is a result of discussions between the Ministry and the Joint Committee. Similarly, the Ministry requests that boards of governors will arrange that when cases are reconsidered the committee which originally reviewed them shall be enlarged by the addition of two members drawn from the medical staff committee of another teaching

hospital, one of whom should be of the specialty of the practitioner whose grading is under review.

Further Appeal

Practitioners whose appeals were considered by a reviewing committee identical with the committee which first graded them will be given a further fortnight in which to lodge an appeal, so that it can be referred to the enlarged committee.

Limitation of Appeals

The Ministry has cancelled the proviso that remuneration at a higher rate as a consequence of any regrading on appeal shall be applicable from the date of regrading only, and not retrospectively, where the regrading is completed after July 5 next. Instead, no appeal lodged with a regional hospital board or board of governors after July 4, 1949, or more than 14 days after the notification of grading to the practitioner, whichever is the later, will be considered. Any practitioner whose appeal is out of time, and who subsequently obtains a consultant post upon the recommendation of an advisory appointments committee constituted under the National Health Service (Appointment of Specialists) Regulations, 1948, will not be able to claim retrospective adjustment of salary at the higher rate from July 5, 1948.

HOSPITAL EYE SERVICE

The Minister has decided that reversible frames and frosted and Chevasse lenses may be supplied under the National Health Service without charge to the patient. Laminated safety lenses may be supplied under the Service, but the patient is normally required to contribute part of the cost.

Glasses may be repaired, except when the damage is due to carelessness, free of charge under the hospital eye service. This condition applies also to those glasses for which the patient has contributed part of the cost.

HOSPITAL BUDGETS

BEDS NOT TO BE CLOSED

The Minister of Health has sent a letter to hospital boards emphasizing that economies should not result in the closing of beds or the reduction of other services essential to the care and welfare of patients. In certain special cases it may be necessary to provide for expenditure on development now in hand involving the opening of additional beds, recruitment of staff, and the provision of other essential services which in the view of the boards are required in the interests of the patients.

The Minister relies on the boards in preparing revised estimates to exercise close financial vigilance and to budget only for services which they are satisfied must be brought into operation during the current financial year. Estimates should be based on the assumption that existing services are to be maintained; they should provide for developments in progress, opening unstaffed beds, and allow for recommended wage increases.

HOSPITAL ENDOWMENTS FUND

The Minister has made regulations (S.I. No. 482, 1949) which provide that, after the discharge out of the Hospital Endowments Fund of certain liabilities transferred to the Minister of Health by the N.H.S. Act, 1946, the balance of the fund will be apportioned between regional hospital boards and hospital management committees by reference to the number of beds in the hospitals which they control. The income of the fund is to be distributed to the boards and committees proportionately to their shares.

GENERAL MEDICAL SERVICES COMMITTEE

Questions of remuneration and of Whitley machinery and arbitration occupied the early part of the meeting on June 2, which was reported in the *Supplement* of June 11 (p. 328). The assessment of payment for temporary residents was then considered. The Remuneration Subcommittee had found that the old method of adjustment as between one area and another no longer justified the labour involved, and recommended that a direct payment be made in respect of every temporary resident, the charge—a direct one on the central fund—to be 15s. for each ordinary "temporary," and, provisionally, 2s. 6d. for each resident in a convalescent home.

The total amount paid out for temporary residents in England and Wales during the first quarter of the present year was £62,298, and for Scotland something like £10,000. A member said that in Blackpool during the same period the number was 4,256, so that evidently a considerable sum of money was involved. Discussion took place on the definition of "temporary resident" and of "treatment." Was the giving of a certificate "treatment"? Dr. Jope said that any person who resided within an area for a period exceeding 24 hours should be regarded as a temporary resident; if the residence was for less than that time the case would constitute an emergency.

The matter was referred again to the Remuneration Subcommittee for action along the lines of the discussion.

Foreign Visitors

Asked whether any steps had been taken to secure safeguards concerning foreign visitors who benefited from the Service during their stay in this country, Dr. Wand, the chairman, explained that the Ministry's view was that, while at any particular moment a certain number of foreign visitors might be in this country participating in the benefits of the Service, it was probable that a corresponding number of British people were abroad, and were therefore outside the responsibility of the practitioner on whose list they were. It was also pointed out that it was much easier to get on the list than off the list.

It was reported that Professor Bradford Hill had agreed to undertake a statistical inquiry for one full year as from Oct. 1 into the work done by general practitioners. Professor Hill had at first expressed himself as doubtful concerning the value of the inquiry if it involved a comparison with pre-war N.H.I. figures covering less than half the population. He had been informed that the purpose of the inquiry was to discover how much work practitioners were now doing and to assess the case for improvement of remuneration on the basis of the number of items of service rendered. He had consented to undertake the task on the understanding that comparisons with the earlier period could not be justified.

The chairman said that the Ministry realized the importance of the problem of inflation of doctors' lists, particularly the cumulative effect of inflation when patients had gone on to lists in two different areas, and a careful check would be made in areas where this was known to occur. It had been promised that the possibility of a central register in line with the census to be taken in 1951 would be looked into.

Position of General-Practitioner Specialists

Dr. Talbot Rogers, in presenting the minutes of a sub-committee which has been considering the position of general-practitioner specialists said that the results of the reviewing boards were far worse than he had expected. To all intents and purposes hardly any general practitioners had been placed in the ranks of specialists. Not only that, but quite a large proportion of the younger people, and some of the older ones, who were doing only specialist work and were regarded by their colleagues in hospital as specialists, and in most cases would in private practice be recognized as such, had been classified as senior hospital medical officers.

The Secretary (Dr. Charles Hill) said that the Joint Committee under Sir Lionel Whitby's chairmanship had been pressing for a proper appeal machinery. The standards of grading varied enormously in different areas, and trouble was blowing up all over the country, not only with regard to general-practitioner specialists but with regard to provincial hospital officers, who had always been regarded as specialists and had

now been graded senior hospital medical officers. It had now been agreed that in future no appointment of senior hospital medical officer should be made except in a very limited field, and the definition of that field was being prepared at the moment.

The committee decided, in view of the widespread dissatisfaction throughout the country, to ask for a proper appeal machinery consisting of a committee none of whose members were concerned with the original assessment.

General Practitioners on Staffs of Cottage Hospitals

An important matter was brought before the committee by Dr. Howie Wood, who produced a form of contract with a cottage hospital in the course of which it was stated that in so far as a general practitioner provided general medical services to a patient on his own domiciliary list he was already remunerated for the work he did in hospital, and in order to provide remuneration for hospital work done for other doctors' patients the hospital management committee had set up a staff fund equal to £25 per occupied bed. This was for assisting at operations and writing up case notes for patients other than the practitioner's own. The sum mentioned was considered to be inadequate in itself and also in comparison with the payment of general practitioners attending convalescent homes. There was an implication in the contract that attendance at the surgeon's behest was part of the general practitioner's duty.

The committee was fully in sympathy with the protest made, and noted this question as one to be dealt with as soon as the present negotiations on remuneration were concluded.

Partnerships and the Inducements Fund

Dr. Katharine Harrower asked the committee to express the opinion that, in the case of partners, inducement payments should be directly related to the work done and not modified by any relationship existing between the partners. She instanced a case in which a husband and wife were in partnership with a third practitioner, and the Ministry assessed the husband and wife together as representing 1½ x, whereas the third practitioner represented 1 x. It was a very short step from this to the cutting down of payments in any partnership, say of father and son.

Dr. Harrower was asked to prepare a short memorandum on this subject so that the matter could be pursued with the Ministry.

Other Business

A report was made on a number of matters which had been discussed with the Ministry of Health. These included the treatment of merchant seamen, mileage payments for maternity cases, emergency claims where calls were frivolous or unjustified, and the question of telephone charges. With regard to this last it was mentioned that the Scottish Department had stated that it was prepared to make some contribution when charges were excessive.

It was reported that a deputation had been received from the National Conference of Friendly Societies to discuss the question of the issue of medical certificates of incapacity to voluntary members of the societies who were not entitled to sickness benefit under the National Insurance Act. These people had to ask their doctors for private certificates. Many doctors gave them gratuitously, but it was a hardship when the persons concerned were required to pay a fee, for the weekly payments were often only a matter of a few shillings.

The committee viewed the request sympathetically, and was of opinion that in such circumstances doctors should not charge for a *pro forma* certificate.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, WallSEND.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

IT IS A FORTUNATE HEAD THAT NEVER ACHED

For providing quick and lasting relief from headache of whatever origin, Veganin* Tablets are especially useful because they do not prevent the patient from continuing his usual occupation. Veganin does not cause drowsiness; it merely obliterates the pain and quiets the nervous manifestations. Veganin is a compound of minimal doses of codeine, phenacetin and acetylsalicylic acid. The synergistic effect of these drugs of related action provides safe analgesic, antipyretic and antispasmodic medication, because the full force of the individual drug is obtained without its accessory manifestations. There is no likelihood of after-effects or habit formation.

Each tablet—118 grs—contains w/w

DOES MEAT MATTER?

We may as well face it. Meat looks like being very scarce for a long time. A meat-hungry public wonders—Does this matter?

We are by tradition and inclination a meat-eating race. Many of us—too many—have acquired the habit of relying mainly on meat for our protein. But so far as nutrition is concerned all experience shows that it is possible for mothers to bear fine children,

for children to grow, for adults to lead full and healthy lives without meat *provided* the diet is well chosen.

Bemax is a useful preparation for patients requiring generous protein intake. Though of cereal origin, its amino acid content ranks it as a source of first-class protein. Moreover its protein content is higher than that of most other common foods. Bemax actually, weight for weight, supplies more protein than does lean beef, and its essential amino-acid analysis renders it of equal protein value with beef.

* * * * *

The recommended daily ounce of Bemax will give one and a half times as much protein as the weekly meat ration (taken as steak). *All this and vitamins, too!*

Why 'Ribena' in Blood Dyscrasias?

Because it is established that vitamin C is an important factor in the proper utilisation of iron by the body, and that, in the treatment of iron-deficiency anaemias, an optimal intake of vitamin C is important. Because, too, clinical experience has proved its value as an adjunct in nutritional anaemias, as also in haemorrhagic states. More specific information will be gladly supplied on request.

Ribena is the pure undiluted juice of fresh ripe blackcurrants with sugar, in the form of a delicious syrup. Being freed from all cellular structure of the fruit, it will not upset the most delicate stomach. It is particularly rich in natural vitamin C (not less than 20 mgm. per fluid ounce) and associated factors.

SCOTTISH G.M.S. SUBCOMMITTEE

A proposal to introduce in Scotland the *Formulary* recently announced by Mr. Bevan as applying to England and Wales was considered by the General Medical Services Subcommittee (Scotland) at a meeting at B.M.A. House, Edinburgh, on May 26. Dr. W. M. Knox presided.

The Department of Health for Scotland pointed out that if the committee approved of the Department's issuing the *Formulary* to practitioners in Scotland they would also send out an accompanying letter explaining the position.

The opinion was expressed that practitioners already made use of their own formulae and it would be to the advantage of the profession to use the national one. It was not so much a question of whether the *Formulary* should be used but rather whether it should be issued. The covering letter made it abundantly clear that there was no intention of introducing compulsion.

The opinion was also expressed that the introduction of the *Formulary* would lead to a general deterioration of the high standard of prescribing which existed in Scotland and to some lazy-mindedness.

The committee agreed to the Department's proposal to issue the *Formulary* together with the covering note.

Filling Vacancies

After discussion the subcommittee indicated its readiness to take part in a meeting with representatives of the Department of Health and the Scottish Association of Executive Councils suggested by the latter body with a view to reducing to a minimum the delay which is taking place in connexion with the filling of vacancies on the medical list of an executive council on the death or retirement of a practitioner. It was decided to transmit to the Department of Health a suggestion that the joint meeting, if held, might take into consideration that where in the filling of a vacancy the local medical committee, executive council, and the Medical Practices Committee are in agreement, in the interests of a general speeding up, there should be no appeal to the Secretary of State. Where there was difference of opinion in any of these bodies, however, appeals should be allowable.

Other Business

The committee received a report on discussions with representatives of Scottish Local Authorities on the question of which services are covered by the fees payable to general practitioners under the National Health scheme. The subcommittee decided to take up with the Department of Health the position of general practitioners under the Service in respect of the domiciliary treatment of venereal diseases.

The committee rejected a proposal by the Department of Health and the pharmacists that, in future, prescription forms should be in duplicate or triplicate. It was admitted that the pharmacists had made out a case for the keeping of a record for their own purposes, but the view was taken that the time was inopportune to ask the practitioner to undertake what is not for his purposes an essential duty.

Constitution of Committee

In connexion with the constitution of the General Medical Services Subcommittee (Scotland) it was decided to recommend to the parent committee that in future each local medical committee in Scotland should have at least one representative on the subcommittee. On a vote it was agreed that the Scottish representatives on the Central General Medical Services Committee should continue to be appointed on an area basis and not by the General Medical Services (Scotland) Subcommittee.

Dangerous Drugs Act: Withdrawal of Authority

The Home Office announces that Dr. Alexander Watt (Peterhead) is no longer authorized to be in possession of or to prescribe those drugs to which the Dangerous Drugs Regulations apply.

WHITLEY MACHINERY AND PUBLIC
HEALTH SALARIES

A meeting of the Public Health Committee of the Association was held on June 3, Dr. James Fenton presiding. An explanation was given of the position with regard to Whitley machinery and arbitration, similar to that which had been made on the previous day to the General Medical Services Committee (Supplement, June 11, p. 328). Under Clause 12 of the amending Bill it appeared that resort to arbitration was possible only with the consent of the Minister. Other types of procedure regarding suitable means of settlement were discussed. The chairman said that a close watch was being kept on the situation from every aspect—that of public health officers as well as general practitioners and consultants and specialists.

The committee considered a letter which had been received from a county medical officer of health suggesting that the Association itself should make known to individual members of local authorities the relevant details of the present dispute with local authorities' associations concerning salaries. This correspondent had found that some members of local authorities thought they were acting in good faith in advertising posts (in the local press, the medical journals being closed to them) at a higher salary than had hitherto obtained. The view of the committee, however, was that it could not approach individual members of local authorities, and that it was the duty of each medical officer of health to explain the position to his council or committee, as, indeed, had been done in the case of the correspondent concerned.

It was reported that a communication had been addressed to the professors of public health at all teaching centres with a view to making the Association's policy known to all successful D.P.H. candidates. Replies had been received from most of the professors testifying their full agreement with the B.M.A. policy and in some cases giving names of candidates so that the Association could communicate direct with them.

Active steps were also being taken to counter any demand by local authorities to employ general practitioners on a sessional basis for the purpose of undertaking duties normally carried out by a whole-time medical officer. When it came to the notice of the head office that a local authority was contemplating such a step, the local Division was informed and requested to advise practitioners in the area against the acceptance of such employment. In the Metropolitan Counties Branch a special appeal had been addressed to all general practitioners, and a letter on this subject had also been sent to all local units of the Association throughout the country.

Fees for Part-time Work

The secretary of the committee (Dr. Kelynack) gave a verbal report of a meeting with representatives of local authorities' associations at the Ministry of Health on May 31 concerning the minimum fees to be paid for part-time work. She said that it was the first time that all these various matters had been assembled in one document. General agreement had been reached on the minimum fees as recommended by the Association for certain services. It was not possible to give a full report as negotiations were still continuing, a further meeting having been arranged for June 20.

The committee expressed its satisfaction with the interim report.

It was reported that on May 4 a meeting of the Askwith Advisory Committee which had been called could not proceed because the County Councils Association, supported by the Urban and Rural District Councils Associations, had refused to take part on the ground that the action of the B.M.A. in refusing public health authority advertisements implied a repudiation of the Askwith Agreement. The Association of Municipal Corporations and the London County Council were represented, and the absence of representatives of the other bodies was generally regarded as highly discourteous. The matter had been reported to the Minister by the independent chairman of the Advisory Committee.

It was reported from the Society of Medical Officers of Health that the council of that body had considered the basis upon which public health service members should contribute to the funds of the British Medical Guild. The society considered

that a levy should be made on the basis of £x for those with salaries of £1,500 and over, by £y for those with salaries of between £1,000 and £1,500, and £z for those with salaries of under £1,000, and that the question of the appropriate contributions to be made should be considered by the General Purposes Committee of the society, when recommendations would be sent to the Association.

ROLE OF THE DIVISIONS IN THE MEDICO-POLITICAL WORK OF THE ASSOCIATION

The Organization Committee has prepared the following memorandum:

The Association has been described as a federation of local medical societies, each having its own administration and rules. Each local unit has autonomy within the limits imposed by the articles and by-laws of the Association, but is linked to others and with the central executive.

The Division provides the means for carrying out locally the main objects of the Association—the promotion of the medical and allied sciences and the maintenance of the honour and interests of the profession. It is to the Division that the individual member should look for help and advice and for the opportunity of meeting his colleagues.

The activities of Divisions can be grouped under four heads: scientific, social, medico-political, and ethical. During the past decade, but chiefly since the end of the war, most Divisions have been preoccupied with medical politics, and the proportion of meetings held to discuss political matters has been unduly high, often at the expense of scientific meetings. It is to be hoped that the balance will be restored, because experience shows that scientific and social occasions attract as a rule larger attendances, and that where the main activity of the Division is political its work tends to pass into the hands of the few who are interested, with harmful effect both to the Division and to the Association as a whole.

Nevertheless, it is important that the Division should continue to foster interest and to take part in medico-political work. Only by this means can the individual member be given the opportunity of criticizing, and through his representative on the Representative Body of shaping, the policy of the Association.

The Representative Body is the parliament of the Association. Once every year it meets to review in detail all the manifold activities of the many committees which, on behalf of the Council, watch over the interests of the profession. It is the responsibility of the Division executive, not only to provide the occasion for discussion of the Council's annual report, but to make every member of the Division feel that his co-operation is needed in order that his representative may attend the Annual Meeting with full knowledge of the views of those he represents.

Two changes likely to affect the position of the Division in relation to medico-political work have followed the introduction of 100% service and the co-ordination of the hospital, public health, and general medical services in a single administrative structure under the National Health Service Act. In the first place more emphasis is placed on negotiation at a national level, the field of local negotiation in which the Division or Branch could conduct its own affairs being correspondingly narrowed. Secondly, special machinery has been extended or devised to deal with terms and conditions of service in the three main fields of practice.

Local Action

While it is true that the field of local political work has been narrowed, much remains. In all questions affecting private practice or services outside the scope of the Act it is still the responsibility of the Division to secure the implementation of Association policy in its area. A review of the work of the Private Practice Committee in recent months will show many examples of questions which can be best dealt with by local units within centrally determined policy. Two instances will suffice to illustrate this point.

The Commissioner of Police for a northern county recently circulated former police surgeons and others and attempted to impose

obligations which were quite unacceptable. This matter has been satisfactorily adjusted by the Branch with the minimum of guidance from headquarters. The Branch arranged a conference of secretaries of Divisions in the county to meet the Commissioner, who has agreed to correct the impression caused, by a further letter in a form agreed by the Branch.

The Prison Commission, with the help of the Ministry of Health, is attempting to form local panels of general practitioners who may be called upon to certify persons on remand where the mental condition and need for detention are in question. A fee is offered which is quite inadequate and at variance with Association policy. Clearly the use of local machinery is necessary in order to warn doctors requested to accept these terms that by so doing they will prejudice the outcome of central negotiations.

Thus the Divisions have a two-way function in local political activity. They may take the initiative when questions arise locally in the first instance, calling on the branch or Headquarters for help, if need be; or they may act as a link between centre and periphery and inform members where individual action or co-operation is required.

In another sphere, closely related to medical politics, the role of the Division is very important. This is in promoting and maintaining good relations between the local profession on the one hand and local government, local institutions, and the lay public on the other. The B.M.A. is now generally accepted as the representative body of the medical profession, but this has not happened fortuitously, and if this position is to be maintained in local communities constant vigilance and action by the Division will be necessary. Good public relations are a necessary condition of success in the medico-political field and are by no means limited to organized press publicity.

The second factor likely to affect the part played by Divisions in medical politics is the establishment of special negotiating machinery for general practitioners and consultants. Committees are now established with autonomy in their respective fields, linked to the Association centrally but with no corresponding link between local organizations. The argument that this situation is not new and that the General Medical Services Committee is only the Insurance Acts Committee under another name is unconvincing. A new situation has arisen through the introduction of a 100% service and through the establishment of similar machinery to represent consultants and specialists. The G.M.S. Committee and the Central Consultants Committee are empowered to act independently in all questions affecting practitioners taking part in the Health Service. Under these circumstances it would seem at first sight that, in a large part of the medico-political field, the local units of the Association must stand aside in order to avoid the dangers of divided counsels and duplication of responsibility. Closer examination of the position shows, however, that for the Division it is a change rather than an abdication of function.

Link in the Profession

Though there is usually cross-representation between the local medical committees and regional consultants committees, making them nominally representative of the whole profession in their areas, these areas are so different and the main interests of the two committees so divergent that in fact they are as separate and distinct as the right and left hands of the medical body-politic. It is for the Division to form the link and to preserve the unity of the profession locally. The Division, because its area is designed to enable members to meet, can attain a much closer contact between its members and its executive than a county or regional committee can have with its constituents. In the latter case the relationship is purely formal, and, once the committee has been elected, formation of policy must remain mainly in the hands of the executive. In the Division, on the other hand, there is opportunity for free criticism and discussion.

Some Divisions, in order to increase facilities for discussion, have formed still smaller units—study groups—and there are clearly advantages in arranging Division areas so that members can meet without having to travel long distances. The proposal that the areas of Divisions and Branches should be revised to conform to the areas of executive councils or regional hospital boards should be resisted.

Fortunately for the sake of the unity of the profession the members of local medical committees and regional consultants committees are usually leading members of the

profession in their areas and as such often hold office in their Divisions; thus there can be a two-way exchange of information, and co-operation is assured. Passive acceptance of this situation, however, is not enough, and an important aim of the Division should be to secure that the Association is adequately represented on these committees.

Another important aspect of the work of the Division in the medico-political field is the education and introduction to medical politics of the younger members, many of whom feel that their interests are not fully understood by their senior colleagues in established practice. The L.M.C. is remote from the assistant, and the consultants committee is far removed from the hospital resident, but both should feel that they can speak and vote at Division meetings and that their views are welcome. Those who are interested in political work can aspire to membership of the executive or office in the Division as a first step towards membership of one of the representative committees or the Representative Body of the Association.

Clearly the role of the Division in providing a meeting-ground for doctors in all branches of practice and a common forum for the expression of medico-political opinion will be, if anything, more important in the future than in the past.

HEARD AT HEADQUARTERS

Silent Eloquence

Many people have expressed themselves forcibly from time to time about the new Health Act, but hardly to the extent of the deaf and dumb speaker of whom Sir Allen Daley spoke the other day. In explaining the Act to a company of deaf and dumb he dislocated three of his fingers.

B.M.A. Films

A feature of the recent Conference of Honorary Secretaries was a film show. The Association is aiming to become, through its film library and bureau, the primary authority on medical films in this country. It is not merely a question of bringing together films which have a medical interest, but of developing a method of presenting medical subjects. To that end a script is being prepared by the Film Committee for a specimen film for potential film producers illustrating how best such a film may be made. A viewing-room at Headquarters, a B.M.A. film caption for attachment to Association films, and arrangements with a film laboratory for the tiling, editing, and conversion of films are other activities on foot.

Not for Nothing

An 'ophthalmic medical practitioner tells us that he has received the following letter about one of his patients: "I understand you examined my daughter's eyes, well I am not satisfied with the report you gave her, do you know much about eyes as you say she has one lazy eye, do you not know of a cure for such an eye, if you do not, I will have to take my daughter to one who does know, and will attempt to put it right, and I will see that we don't pay national insurance for nothing."

One Mosquito

One would like to have the comments of a Ross Institute investigator on a statement made by Lord Winstler, the late Governor of Cyprus, at a meeting of the Royal Empire Society. Lord Winstler painted an idyllic picture of Cyprus (in every respect except the political) and referred in particular to its immunity from malaria. The island has been scourged by malaria for generations, and there used to be districts where malaria affected the entire population. But now the place has been cleaned up and not a case remains, as Drs. Shelley and Aziz recorded recently in this *Journal*. Lord Winstler then said that during his governorship an investigator came out from the Ross Institute to see what had been done about the malaria-carrying mosquito, and he was able to find only one on the whole island. "And I am absolutely certain," added his lordship, "that he brought it out with him!"

Questions Answered

Emergency Fee

Q.—*I was summoned by the local police to appear at the station to identify a girl brought to them with "loss of memory." I went and identified the patient and took her home. As for payment, the officer in charge of the station said that, since I was a National Health Service doctor, no "certificate" could be issued to me and that I therefore would receive no payment from the police. Is this kind of activity part of my duty under the N.H.S.? If not, to whom do I apply for remuneration?*

A.—Where a practitioner is asked to attend a patient as a result of an accident or other emergency he is entitled to claim an emergency fee from the executive council if the patient is not on his list. The only exception is where a fee under the Road Traffic Act can be claimed. The police are responsible for a fee only where an examination or report is undertaken at their request.

Dental Haemorrhages

Q.—*During the past few weeks I have been called out on several occasions to arrest haemorrhage after dental extractions. On whom does this responsibility lie—the dentist or the doctor?*

A.—The arrest of dental haemorrhage is the responsibility of the dental surgeon who undertook the extraction. When the dentist is not immediately available the patient often calls upon his normal medical attendant. In the Ministry's view this service forms part of the practitioner's normal obligations to his patients, but the Association is disputing this interpretation and is pressing for an appropriate fee to be paid when the general practitioner is called out.

Patient on Public List

Q.—*A few weeks ago I received a request to visit a patient who, although actually on my register of insured persons, had some time previously moved to a district in which I have not undertaken to visit State patients. I explained this on the phone, and was informed that the patient was aware of this, but was anxious that I should continue to attend the family as private patients. I visited the patient for several days. I am aware that I should be at liberty to refuse to visit the patient and instruct them to call in a doctor who attends State patients in their particular district, but am I at liberty to charge a visiting fee, notwithstanding the fact that they were at the time on my list of State patients?*

A.—As the patient concerned is included on your public list you are debarred by the regulations from receiving any fee in respect of medical attendance or treatment given.

HONG KONG AND CHINA BRANCH

The Branch has about 175 members, of whom about 6/7 are in Hong Kong and the rest in China. Seventeen meetings have been held in Hong Kong since the war, at which members have read papers, films have been shown, and laboratory and clinical demonstrations have been arranged. The Branch owns a library in the centre of the town and has recently purchased some 50 new books.

Each month the honorary secretary, Dr. D. W. Gould, makes a précis of the proceedings of the Branch Council, which is circulated to all members both in Hong Kong and China, and he includes with it information on any matters of general interest which have arisen during the month.

The Branch Council is active and effective. Forty-five members of the Branch in Hong Kong are Chinese, and the Branch co-operates closely with the Hong Kong Branch of the Chinese Medical Association.

Most of the members in China itself are medical missionaries. It appears that the Communists are allowing medical missionaries to continue their work in the areas so far conquered, provided the missionaries confine themselves to medicine and abstain from religious or political activity.

British Medical Association

ONE HUNDRED AND SEVENTEENTH ANNUAL MEETING, HARROGATE, JUNE 24 TO JULY 1, 1949

President-Elect: C. W. CURTIS BAIN, M.C., D.M., F.R.C.P., Senior Physician, Harrogate General Hospital.
Local General Secretary: D. D. PAYNE, M.D., D.P.H. } B.M.A. Office, Royal Baths, Harrogate.
Executive Officer: G. A. PECK, B.Sc. }
Local Science Secretary: J. V. WILSON, M.D., M.R.C.P., Department of Pathology, Harrogate General Hospital.

PROGRAMME

SCIENTIFIC SECTIONS

The following Sections will meet on Four Days:

MEDICINE

President: Professor R. E. TUNBRIDGE, O.B.E., M.Sc., M.D., F.R.C.P. (Leeds).

Vice-Presidents: Professor H. W. FULLERTON, M.D., F.R.C.P. (Aberdeen); R. R. BOMFORD, D.M., F.R.C.P. (London); Professor A. P. THOMSON, M.C., M.D., F.R.C.P. (Birmingham).

Hon. Secretaries: T. G. REAH, M.D., M.R.C.P., 4, Spring Grove, Harrogate; J. L. LOVIBOND, M.D., F.R.C.P., 81, Harley Street, W.1.

Official Reporter: Dr. K. M. A. PERRY.

Meeting-place: Harrogate Hydro.

Tuesday, June 28.—10 a.m., *Discussion*: Diabetes Mellitus. To be opened by Dr. R. D. LAWRENCE (London), followed by Professor R. E. TUNBRIDGE (Leeds), Insulin and Diet; Mr. H. H. FOURACRE BARNES (London) and Dr. CHARLES ROLLAND (Edinburgh), Pregnancy Aspects; Mr. D. A. HALL, Ph.D. (Leeds), Rapid Blood Sugar Estimations; Dr. R. G. PALEY (Leeds), Skin Complications of Insulin Injections; and Dr. A. J. BALLANTYNE (Glasgow), Ocular Complications. Dr. E. P. JOSLIN (Boston, U.S.A.) will be present and take part in the discussion.

Wednesday, June 29 (Combined Meeting with Section of Surgery).—10 a.m., *Discussion*: Treatment of Peptic Ulcers. To be introduced and summarized by Sir HENRY COHEN (Liverpool). Opening paper by the late Mr. A. HEDLEY VISICK (York) to be read by Dr. C. N. PULVERTAFT (York), followed by Dr. RICHARD DOLL (London), Sociological Aspects; and Mr. A. D. BEATTIE (Leicester), Surgical Aspect.

Thursday, June 30.—10 a.m., *Papers*: (1) Streptomycin, by Dr. GEOFFREY MARSHALL (London); (2) Radioactive Substances in Clinical Medicine, by Dr. RUSSELL FRASER (London); (3) Anticoagulants, by Professor H. W. FULLERTON (Aberdeen).

Friday, July 1.—10 a.m., *Discussion*: Cirrhosis of the Liver. To be opened by Dr. N. H. MARTIN (London), Aetiology and Pathology, followed by Dr. N. H. K. HAGGIE (London), Alcohol in Cirrhosis; Mr. J. E. RICHARDSON (London), Surgical Aspects; and Dr. E. R. CULLINAN (London), Clinical Aspects and Summary. *Paper*: Salicylate Therapy in Acute Rheumatism, by Dr. G. WATKINSON (Leeds).

Thursday, June 30, and Friday, July 1.—2.30 p.m., Royal Bath Hospital. *Demonstration*: The Role of Surgery in Rheumatism. "Movement is Life" (Lucas-Championnière).

OBSTETRICS AND GYNAECOLOGY

President: Professor A. M. CLAYE, M.D., F.R.C.S., F.R.C.O.G. (Leeds).

Vice-Presidents: GLADYS KAY, M.D. (Harrogate); Professor T. N. A. JEFFCOATE, M.D., F.R.C.S.Ed., F.R.C.O.G. (Liverpool); ARNOLD L. WALKER, M.B., F.R.C.S., F.R.C.O.G. (London).

Hon. Secretaries: C. RUTHERFORD MORISON, M.D., M.R.C.O.G., 2, Lancaster Road, Harrogate; Miss JOSEPHINE BARNES, D.M., F.R.C.S., M.R.C.P., M.R.C.O.G., 7, Wimpole Street, W.1.

Official Reporter: Dr. D. GORDON LENNON.

Meeting-place: Prince of Wales Hotel.

Tuesday, June 28.—10 a.m., *Discussion*: Breech Presentation and its Management. To be opened by Mr. R. NEWTON (Manchester), followed by Mr. C. M. MARSHALL (Liverpool), Mr. B. L. JEFFRESON (Leeds), and Dr. J. LOVSET (Norway).

Wednesday, June 29 (Combined Meeting with Section of Radiology).—10 a.m., *Discussion*: The Value of X-ray in

Assessing Disproportion. To be opened jointly by Professor CHASSAR MOIR (Oxford) and Dr. J. BLAIR HARTLEY (Manchester), followed by Miss MEAVE KENNY (London) and Dr. S. JOSEPHS (Newcastle-upon-Tyne).

Thursday, June 30 (Combined Meeting with Section of Dermatology).—10 a.m., *Discussion*: Pruritus Vulvae. To be opened by Professor T. N. A. JEFFCOATE (Liverpool) and Dr. G. A. GRANT PETERKIN (Edinburgh), followed by Dr. ELIZABETH HUNT (London) and Dr. C. J. MACKINLAY (Glasgow).

Friday, July 1.—10 a.m., *Discussion*: Functional Uterine Haemorrhage. To be opened by Mr. V. B. GREEN-ARMYtage (London), followed by Dr. P. M. F. BISHOP (London) and Dr. T. N. MACGREGOR (Edinburgh).

PATHOLOGY AND BACTERIOLOGY

President: Professor R. J. V. PULVERTAFT, O.B.E., M.D., F.R.C.P. (London).

Vice-Presidents: Professor T. F. HEWER, M.D., F.R.C.P. (Bristol); J. G. GREENFIELD, M.D., F.R.C.P. (London); A. H. T. ROBB-SMITH, M.D., M.R.C.P. (Oxford).

Hon. Secretaries: J. V. WILSON, M.D., M.R.C.P., Harrogate General Hospital, Harrogate; Professor H. A. MAGNUS, M.D., Department of Pathology, King's College Hospital, Denmark Hill, S.E.5.

Official Reporter: Professor ROBERT CRUICKSHANK.

Meeting-place: Grand Hotel.

Tuesday, June 28.—9.45 a.m., *Opening of Pathological Museum, Royal Bath Hospital, Cornwall Road*, by Professor M. J. STEWART, LL.D., F.R.C.P., F.R.F.P.S., F.F.R. (Leeds). 10 a.m., *Discussion*: The Laboratory Diagnosis and Prevention of Whooping-cough. To be opened by Professor R. CRUICKSHANK (London), followed by Dr. W. C. COCKBURN (London), and Dr. D. G. EVANS (Manchester). 12 noon, *Discussion*: The Care and Treatment of Laboratory Animals. To be opened by Dr. JEAN VINTNER (Technical Secretary, U.F.A.W.), followed by Professor A. N. WORDEN (Chief Biochemist to the Animal Health Trust).

Wednesday, June 29 (Combined Meeting with Section of Tropical Medicine).—10 a.m., *Discussion*: Fat Metabolism and the Sprue Syndrome. To be opened jointly by Professor A. C. FRAZER (Birmingham) and Dr. DOUGLAS BLACK (Manchester), followed by Dr. K. D. KEELE (London) and Dr. A. W. D. LEISHMAN (Sheffield). During the discussion Sir PHILIP MANSON-BAHR will show lantern slides illustrating the lesions of the tongue in sprue.

Thursday, June 30.—10 a.m., *Discussion*: Chemotherapy in the Treatment of Malignant Disease. To be opened by Professor E. C. DODDS (London), followed by Sir STANFORD CADE (London), Professor A. HADDOW (London), and Professor F. DICKENS (London).

Friday, July 1.—10 a.m., *Papers*: (1) The Pathological Anatomy of Hypersensitivity Reactions in Man, by Professor HILDING BERGSTRAND (Stockholm). (2) Temporal Arthritis, by Dr. C. V. HARRISON (London). (3) Vascular Changes in Diabetes, with Particular Reference to Retinal and Renal Changes, by Dr. N. ASHON (London).

RADIOLOGY

President: J. L. A. GROUT, F.R.C.S.Ed., D.M.R.E., F.F.R. (Sheffield).

Vice-Presidents: C. G. HITCHCOCK, M.R.C.S., L.R.C.P. (Harrogate); J. ALEX. THOMSON, M.B., Ch.B., D.M.R.E. (Harrogate); Professor BRIAN W. WINDEYER, F.R.C.S.Ed., D.M.R.E., F.F.R. (London).

Hon. Secretaries: C. N. PULVERTAF, M.B., B.Ch., D.M.R.E., York County Hospital, York; JOHN R. NUTTALL, M.D., F.F.R., D.M.R., Radium Department, General Infirmary, Leeds.

Official Reporter: Mr. COOPER.

Tuesday, June 28. Meeting-place: Queen Hotel (Therapeutic Meeting).—10 a.m., *Discussion:* The Scope and Limitation of Radiotherapy. To be opened jointly by Dr. J. S. FULTON (Liverpool) and Dr. CHESTER WILLIAMS (Bradford).

Wednesday, June 29. Meeting-place: Prince of Wales Hotel (Combined Meeting with Section of Obstetrics and Gynaecology).—10 a.m., *Discussion:* The Value of X-ray in Assessing Disproportion. To be opened jointly by Professor CHASSAR MOIR (Oxford) and Dr. J. BLAIR HARTLEY (Manchester), followed by Miss MEAVE KENNY (London) and Dr. S. JOSEPHS (Newcastle-upon-Tyne).

Wednesday, June 29. Meeting-place: Prince of Wales Hotel (Therapeutic Meeting).—10 a.m., *Discussion:* Radiotherapy in Spondylitis Ankylopoietica and Osteoarthritis. To be opened by Dr. E. L. GWENDOLEN HILTON (London), followed by Dr. MARGARET D. SNELLING (London) and Dr. L. JANET MALLENDER (Leeds).

Thursday, June 30. Meeting-place: Majestic Hotel (Combined Meeting with Section of Cardiology).—10 a.m., *Discussion:* Angiocardiography. To be opened jointly by Dr. FRANCES GARDNER (London), Interpretation of Normal Angiocardiograms; of those seen in Cases of Cyanotic Heart Disease, and in Aortitis and Aortic Aneurysm; and Dr. J. WILKIE (Sheffield), Technical Considerations; Demonstration of Angiocardiograms. Followed by Dr. K. D. KEELE (London), Angiocardiograms in Acyanotic Heart Disease; Dr. T. H. HILLS (London), Angiocardiograms in Cyanotic Heart Disease; and Dr. F. JACKSON (London), Present Trends in North American Clinics.

Friday, July 1. Meeting-place: Queen Hotel (Diagnostic Meeting).—10 a.m., *Discussion:* Radiology of Joints. To be opened by Dr. E. DUFF GRAY (Manchester), followed by Dr. P. H. WHITAKER (Liverpool) and Dr. J. B. KING (Edinburgh).

SURGERY

President: T. V. PEARCE, M.D., F.R.C.S. (Harrogate).

Vice-Presidents: H. HAMILTON STEWART, F.R.C.S. (Bradford); IAN J. FRASER, D.S.O., O.B.E., F.R.C.S. (Belfast); Sir CECIL P. G. WAKELEY, F.R.C.S., F.R.A.C.S., F.R.S.Ed. (London).

Hon. Secretaries: GORDON N. BAILEY, M.A., M.B., F.R.C.S., 2, Lancaster Road, Harrogate; RODNEY SMITH, M.S., F.R.C.S., 6, Devonshire Place, W.1.

Official Reporter: Professor IAN AIRD.

Tuesday, June 28. Meeting-place: Majestic Hotel.—10 a.m., *Discussion:* Prostatic Obstruction. To be opened by Mr. H. HAMILTON STEWART (Bradford), followed by Mr. WILSON HEY (Manchester), Mr. ASHTON MILLER (Bristol), and Mr. JOHN SWINNEY (Newcastle-upon-Tyne).

Wednesday, June 29 (Combined Meeting with Section of Medicine). Meeting-place: Harrogate Hydro.—10 a.m., *Discussion:* Treatment of Peptic Ulcers. To be introduced and summarized by Sir HENRY COHEN (Liverpool). Opening Paper by the late Mr. A. HEDLEY VISICK (York) to be read by Dr. C. N. PULVERTAF (York), followed by Dr. RICHARD DOLL (London), Sociological Aspects; and Mr. A. D. BEATTIE (Leicester), Surgical Aspect.

Thursday, June 30 (Combined Meeting with Section of Neurology and Psychiatry). Meeting-place: Majestic Hotel.—10 a.m., *Discussion:* The Treatment, After-Treatment, and Sequelae of Closed Injuries to the Head. To be opened by Professor NORMAN MCOMISH DOTT (Edinburgh), followed by Dr. W. RITCHIE RUSSELL (Oxford), Rehabilitation after Head Injury; and Dr. E. STENGEL (Chichester), Psychiatric Aspects of Head Injury. 2.30 p.m., *Occasional Paper:* The Mechanism of Speech and the Repair of a Cleft Palate, by Mr. MICHAEL OLDFIELD (Leeds), illustrated by coloured film and drawings.

Friday, July 1. Meeting-place: Majestic Hotel.—10 a.m., *Discussion:* Pain in the Right Iliac Fossa. To be opened by Dr. A. FULLERTON (Batley), followed by Professor D. CHAMBERLAIN (Leeds), Mr. R. K. BOWES (London), and Mr. G. H. MACNAB (London).

Thursday, June 30, and Friday, July 1.—2.30 p.m., Royal Bath Hospital. Demonstration: The Role of Surgery in Rheumatism. "Movement is Life" (Lucas-Championnière).

The following Sections will meet on Two Days:

ANAESTHETICS

President: Professor R. R. MACINTOSH, D.M., F.R.C.S.Ed., D.A. (Oxford).

Vice-Presidents: B. L. S. MURTAGH, M.B., Ch.B., F.F.A.R.C.S., D.A. (Birmingham); H. B. WILSON, M.B., Ch.B., D.P.H., F.F.A.R.C.S., D.A. (Aberdeen); GEOFFREY ORGANE, M.D., F.F.A.R.C.S., D.A. (London).

Hon. Secretaries: W. M. JONES, M.B., B.S., D.A., 4, South Drive, Harrogate; J. ALFRED LEE, M.R.C.S., L.R.C.P., F.F.A.R.C.S., D.A., 73, King's Road, Westcliff-on-Sea.

Official Reporter: Dr. W. W. MUSHIN.

Meeting-place: Queen Hotel.

Wednesday, June 29.—10 a.m., Discussion: Post-operative Pulmonary Complications. To be opened jointly by Dr. H. J. V. MORTON (Uxbridge) and Dr. E. M. BUZZARD (Oxford), followed by Mr. DONALD BARLOW (London), Dr. DONALD TEARE (London), and Dr. JOAN MILLAR (Newcastle-upon-Tyne).

Thursday, June 30.—10 a.m., Discussion: Dental Anaesthesia. To be opened by Dr. W. S. MCCONNELL (London), followed by Dr. STEPHEN COFFIN (London) and Dr. FRED A. BANNISTER (Chester). 11.15 a.m., *Discussion:* The Use of Continuous Caudal and Peridural Analgesia in Obstetrics, Surgery, and Therapeutics. To be opened by Dr. ROBERT A. HINGSON (Johns Hopkins, Baltimore). (Note.—This discussion may be continued at 2.30 p.m.)

ANATOMY AND PHYSIOLOGY

President: Professor JOHN KIRK, M.B., Ch.B., F.R.C.S.Ed. (London).

Vice-Presidents: Professor A. HEMINGWAY, M.Sc., M.B., Ch.B. (Leeds); Professor FRANCIS DAVIES, M.D. (Sheffield); Professor C. McLAREN WEST, M.C., M.B., B.Ch. (Cardiff).

Hon. Secretaries: E. J. FIELD, M.D., M.S., Department of Anatomy, University of Bristol; R. J. SCOTHORNE, B.Sc., M.B., Ch.B., Anatomy Department, School of Medicine, Leeds, 2.

Official Reporters: Professor A. HEMINGWAY and Dr. E. J. FIELD.

Note: On Tuesday, June 28, *Physiology* and *Anatomy* will meet as separate Sections, but there will be a united meeting on Wednesday, June 29.

Physiology—Tuesday, June 28. Meeting-place: Cairn Hydro.—10 a.m., *Symposium* on the Control of Activity in the Gastro-intestinal Tract. *Speakers:* Professor R. A. GREGORY (Liverpool), Motility of the Small Intestine in Relation to Feeding; Dr. A. A. HARPER (Manchester), The Control of Gastric and Pancreatic Secretion; Dr. R. E. DAVIES (Sheffield), Secretory Mechanisms and Their Control; Dr. J. N. HUNT (London), Studies of Gastric Motility.

Anatomy—Tuesday, June 28. Meeting-place: Prince of Wales Hotel.—10 a.m., *Symposium* on Muscle Structure and Function. *Speakers:* Professor W. E. LE GROS CLARK (Oxford), The Vascularization of Muscle, with Special Reference to Ischaemic Necrosis and Reparative Processes; Dr. R. BARER (Oxford), The Organization of the Muscle Fibre; Dr. R. E. M. BOWDEN (London), Some Aspects of Denervation and Re-innervation of Human Voluntary Muscle; Mr. W. F. FLOYD (London), Clinical Value of Electro-myographic Studies; and Professor W. T. ASTBURY (Leeds), The Muscle as a Molecular Machine.

Wednesday, June 29. Meeting-place: Cairn Hydro.—10 a.m., *Symposium* on the Anatomy and Physiology of the Skin. *Speakers:* Professor H. BARCROFT (London), Factors Regulating Blood Flow in the Skin; Dr. C. A. KEELE (London), The Control of Sweating; Dr. R. E. BILLINGHAM (Birmingham), The Anatomical Basis of Epidermal Pigmentation in Man; and Dr. G. WEDDELL (Oxford), The Pattern of Cutaneous Innervation.

CARDIOLOGY

President: Sir JOHN PARKINSON, M.D., F.R.C.P. (London).

Vice-Presidents: JOHN R. H. TOWERS, M.D., F.R.C.P. (Leeds); Professor J. CRIGHTON BRAMWELL, M.D., F.R.C.P. (Manchester); D. EVAN BEDFORD, M.D., F.R.C.P. (London).

Hon. Secretaries: D. R. CAMERON, M.D., M.R.C.P., 14, Clifton, York; GRAHAM W. HAYWARD, M.D., F.R.C.P., St. Bartholomew's Hospital, E.C.1.

Official Reporter: Dr. PAUL WOOD.

Meeting-place: Majestic Hotel.

Thursday, June 30 (Combined Meeting with Section of Radiology).—10 a.m., *Discussion:* Angiocardiography. To be opened jointly by Dr. FRANCES GARDNER (London), Interpretation of Normal Angiocardiograms; of those seen in Cases of Cyanotic Heart Disease, and in Aortitis and Aortic Aneurysm; and Dr. J. WILKIE (Sheffield), Technical Considerations: Demonstration of Angiocardiograms. Followed by Dr. K. D. KEELE (London), Angiocardiograms in Acyanotic Heart Disease; Dr. T. H. HILLS (London), Angiocardiograms in Cyanotic Heart Disease; and Dr. F. JACKSON (London), Present Trends in North American Clinics.

Friday, July 1.—10 a.m., Simulation of Heart Disease by Other Conditions. To be opened by Dr. RAE GILCHRIST (Edinburgh), followed by (a) Simulation by Pulmonary Conditions, by Dr. J. CLIFFORD HOYLE (London); (b) Simulation by Gastro-intestinal Conditions, by Dr. S. W. PATTERSON (Ruthin Castle); (c) Simulation by Psychoneuroses, by Dr. WILLIAM PHILLIPS (Cardiff). 12 noon, *Discussion:* The Treatment of Obstinate Heart Failure. To be opened by Dr. D. EVAN BEDFORD (London).

CHILD HEALTH

President: Professor C. W. VINING, M.D., F.R.C.P., D.P.H. (Leeds).

Vice-Presidents: Professor R. S. ILLINGWORTH, M.D., F.R.C.P., D.P.H., D.C.H. (Sheffield); A. A. E. NEWTH, M.B., B.S., D.P.H. (Nottingham); Professor W. S. M. CRAIG, M.D., F.R.C.P.Ed., F.R.S.Ed. (Leeds).

Hon. Secretaries: L. J. PROSSER, M.B., Ch.B., D.C.H., 11, Ripon Road, Harrogate; T. COLVER, M.D., M.R.C.P., 4, Claremont Place, Sheffield, 10.

Official Reporter: Professor W. S. CRAIG.

Meeting-place: Grand Hotel.

Wednesday, June 29.—10 a.m., *Discussion:* Common Feeding Difficulties in Infancy. To be opened by Professor R. S. ILLINGWORTH (Sheffield), followed by Dr. FRANCES CHARLOTTE NASH (York), Dr. STANLEY G. GRAHAM (Glasgow), and Dr. JEAN MACKINTOSH (Birmingham). *Discussion:* Domiciliary Care of the Premature Child. To be opened by Dr. F. J. W. MILLER (Newcastle-upon-Tyne).

Thursday, June 30 (Combined Meeting with Section of Preventive Medicine).—10 a.m., *Discussion:* Behaviour Difficulties in Childhood. To be opened by Dr. MILDRED CREAK (London), followed by Professor C. W. VINING (Leeds) and Dr. W. S. MACDONALD (Leeds). 3 p.m., Demonstration of Cases and Radiographs of Tuberculosis in Childhood, at Scotton Banks Sanatorium, by Dr. VINCENT RYAN (Knaresborough).

DERMATOLOGY

President: J. T. INGRAM, M.D., F.R.C.P. (Leeds).

Vice-Presidents: BRIAN F. RUSSELL, M.D., M.R.C.P., D.P.H. (London); P. B. MUMFORD, M.D., F.R.C.P. (Manchester); GEOFFREY HODGSON, M.B.E., M.D. (Cardiff).

Hon. Secretaries: S. T. ANNING, M.D., M.R.C.P., 5a, Shaw Lane, Leeds, 6; H. J. WALLACE, M.D., M.R.C.P., 80, Harley Street, W.1.

Official Reporter: Dr. J. T. INGRAM.

Thursday, June 30. *Meeting-place:* Prince of Wales Hotel (Combined Meeting with Section of Obstetrics and Gynaecology).—10 a.m., *Discussion:* Pruritus Vulvae. To be opened by Professor T. N. A. JEFFCOATE (Liverpool) and Dr. G. A. GRANT PETERKIN (Edinburgh), followed by Dr. ELIZABETH HUNT (London).

Friday, July 1. *Meeting-place:* Majestic Hotel.—10 a.m., *Discussion:* Psoriasis. To be opened by Dr. H. W. BARBER (London), followed by Dr. BRIAN F. RUSSELL (London) and Dr. J. H. TWISTON DAVIES (Manchester). *Occasional Paper:* The Uses and Abuses of Chemotherapy in Dermatology, by Dr. F. F. HELLIER (Leeds). 2.30 p.m., Clinical Meeting at Royal Bath Hospital.

NEUROLOGY AND PSYCHIATRY

President: W. RUSSELL BRAIN, D.M., F.R.C.P. (London).

Vice-Presidents: W. R. HENDERSON, O.B.E., M.B., Ch.B., F.R.C.S. (Leeds); DAVID ROBERTSON, M.D. (York); R. G. GORDON, M.D., F.R.C.P.Ed. (Bath).

Hon. Secretaries: JAMES VALENTINE, M.B., Ch.B., D.P.M., Scalebor Park, Burley-in-Wharfedale, near Leeds, Yorks; HELEN E. DIMSDALE, M.D., F.R.C.P., 41, Devonshire Street, Portland Place, London, W.1.

Official Reporters: Dr. W. RITCHIE-RUSSELL (June 30 only) and Dr. PURDON MARTIN.

Meeting-place: Majestic Hotel.

Wednesday, June 29.—10 a.m., *Discussion:* Intractable Pain. To be opened jointly by Dr. J. PURDON MARTIN (London) and Mr. WYLIE MCKISSOCK (London), followed by Dr. E. B. STRAUSS (London), Psychiatric Aspect; and Dr. ANDREW WILSON (London), Pharmacological Aspect.

Thursday, June 30 (Combined Meeting with Section of Surgery).—10 a.m., *Discussion:* The Treatment, After-Treatment, and Sequelae of Closed Injuries to the Head. To be opened by Professor NORMAN MCOMISH DOTT (Edinburgh), followed by Dr. W. RITCHIE RUSSELL (Oxford), Rehabilitation after Head Injury; and Dr. E. STENGEL (London), Psychiatric Aspects of Head Injury.

OCCUPATIONAL HEALTH

President: Professor R. E. LANE, M.D., F.R.C.P. (Manchester).

Vice-Presidents: Professor G. P. CROWDEN, O.B.E., D.Sc., M.R.C.P. (London); F. S. COOKSEY, O.B.E., M.D., D.Phys.M. (London); W. BLOOD, M.R.C.S., L.R.C.P., D.I.H. (London).

Hon. Secretaries: CHARLES CRESDEE, M.R.C.S., Wits End, Fixby Road, Huddersfield; R. S. F. SCHILLING, M.D., D.P.H., Department of Occupational Health, University of Manchester, Manchester, 13.

Official Reporter: Dr. R. S. F. SCHILLING.

Meeting-place: Majestic Hotel.

Wednesday, June 29.—10 a.m., *Discussion:* The Development of a Comprehensive Medical Service for Industry. To be opened by Dr. DONALD STEWART (Birmingham), followed by Dr. STUART LAIDLAW (Glasgow) and Dr. N. J. COCHRAN (Burton-upon-Trent).

Thursday, June 30.—10 a.m., *Discussion:* Tuberculosis and Occupation. (1) Tuberculosis in the Boot and Shoe Trade, by Dr. ALICE STEWART (Harrow-on-the-Hill); (2) Mass Radiography in Industry, by Dr. W. POINTON DICK (Denham); (3) Rehabilitation and Resettlement, by Dr. F. R. G. HEAF (London).

OPHTHALMOLOGY

President: JAMES FISON, M.D. (Harrogate).

Vice-Presidents: JOHN MARSHALL, M.C., M.B., Ch.B., D.O.M.S. (Glasgow); N. P. R. GALLOWAY, M.B., Ch.B., D.O. (Nottingham); A. B. NUTT, M.B., B.S. (Sheffield).

Hon. Secretaries: JANE A. M. SHEPHERD, M.B., Ch.B., D.O.M.S., 39, Harlow Oval, Harrogate; P. D. TREVOR-ROPER, M.B., B.Ch., F.R.C.S., D.O.M.S., 126, Harley Street, W.1.

Official Reporter: Mr. J. H. DOGGART.

Meeting-place: Masonic Hall, Harrogate.

Thursday, June 30.—10 a.m., *Discussion:* Ophthalmology in Relation to Diseases of the Skin. To be opened by Mr. J. H. DOGGART (London), followed by Dr. ALICE CARLTON (Oxford) and Dr. I. B. SNEDDON (Sheffield). Afternoon, *Occasional Papers:* (1) Scleromalacia Perforans, by Mr. H. V. INGRAM (Newcastle-upon-Tyne); (2) Angiomatosis Retinae, by Mr. A. G. CROSS (London); (3) Watery Eye, by Mr. JOHN MARSHALL (Glasgow).

Friday, July 1.—10 a.m., *Occasional Papers:* (1) Toxoplasmosis, by Mr. A. B. NUTT (Sheffield); (2) Practical Ophthalmology in Spain and Holland in 1948, by Mr. JOHN FOSTER (Leeds).

ORTHOPAEDICS

President: R. BROOMHEAD, M.B., F.R.C.S. (Leeds).

Vice-Presidents: C. GORDON IRWIN, M.B., F.R.C.S.Ed. (Newcastle-upon-Tyne); H. JACKSON BURROWS, M.D., F.R.C.S., F.R.A.C.S. (London); F. W. HOLDSWORTH, M.B., M.Ch., F.R.C.S. (Sheffield).

Hon. Secretaries: IAN LAWSON DICK, M.B., Ch.M., F.R.C.S.Ed., 2, Walmer Villas, Manningham Lane, Bradford; J. P. CAMPBELL, M.B., Ch.B., F.R.C.S.Ed., 1, Tavistock Avenue, Mapperley Park, Nottingham.

Official Reporter: Mr. NORMAN CAPENER.

Meeting-place: Majestic Hotel.

FRAZER (Birmingham) and Dr. DOUGLAS BLACK (Manchester), followed by Dr. K. D. KEELE (London) and Dr. A. W. D. LEISHMAN (Sheffield).

HOTEL AND LODGING ACCOMMODATION

Accommodation in Harrogate during the time of the B.M.A. Annual Meeting is now extremely limited, and members who have not made their reservations should do so at once. (For list of hotels, see *Supplement*, April 23, p. 243.)

REGULATIONS REGARDING DRESS

Robes with hoods are to be worn at: the Official Religious Service, Tuesday, June 28, at 3 p.m.; the President's Address, Tuesday, June 28, at 8.30 p.m.; the President's Reception, Tuesday, June 28, at 9.30 p.m.; the Mayor's Reception, Wednesday, June 29, at 8.30 p.m.; the Roman Catholic Service, Thursday, June 30, at 3 p.m.

Robes may be hired from Messrs. Ede and Ravenscroft, Ltd., 93, Chancery Lane, W.C.2, and should be sent direct to the hotel or other accommodation in which the hirer is resident and not to the Reception Office.

Evening Dress (Tails or Dinner Jacket) with Decorations is to be worn at the President's Reception, Civic Reception, and Annual Dinner. Dress is optional for the Representatives' Dinner.

REGISTRATION FEE, AT ANNUAL MEETINGS

The expenditure arising in connexion with the Annual Meetings has in the past been met from a guarantee fund raised by the local profession, supplemented by a grant from the Council of the Association. The Council considers that the time has come when the proportion of the expenses falling upon the local profession should be minimized. With this object in view the Council, while continuing the central grant, has decided that members attending the Annual Meeting (other than members of the Representative Body and overseas visitors) should be asked to pay a fee of one guinea towards the expenses of the meeting. The fee of one guinea will be payable when members register at the Reception Office, Sun Pavilion, Harrogate.

OFFICIAL RELIGIOUS SERVICE

The Official Religious Service will be held in St. Peter's Church, Harrogate, on Tuesday, June 28, and the sermon will be given by His Grace the Archbishop of York. The service will be broadcast in the Northern Programme, and the church is likely to be full. It has therefore been decided to issue tickets for the Procession, for which academic dress is required. It will then be possible to ascertain how many seats will be available for wives and friends. Application for tickets, which will admit to the robing-room at the Royal Hall, can be made on the enclosed form. The tickets themselves will be issued at the Reception Office, Sun Pavilion, from 2 p.m. on Monday, June 27. Members of Council and Representatives will be able to obtain their tickets for robing at the A.R.M. Inquiry Office, Royal Hall, from Friday, June 24. Should the number of members intending to take part in the procession be less than the seating accommodation at the church, additional tickets for admission to the church will be issued on Tuesday morning in order of application. Those receiving them must be in their seats by 2.30 p.m. Those taking part in the procession should reach the Royal Hall by 2 p.m., as all the congregation must be seated before the broadcast begins at 3 p.m.

EXCURSION PROGRAMME

Excursions to places of interest in the neighbourhood of Harrogate are likely to prove a great attraction to the doctors and their wives attending the Annual Meeting. Arrangements for transport and refreshments have already had to be made and the numbers fixed for each excursion. In order to avoid disappointment those wishing to take part in any of the excursions* should therefore fill in the enclosed form and send it, with the appropriate payment, to the Executive Officer, B.M.A. Office, Royal Baths, Harrogate, Yorks. Cheques should be made payable to "The British Medical Association" and crossed. Excursions 6, 24, and 27 are fully booked.

Applications will be acknowledged at once, but the reserved tickets will be collected at the Reception Office, Sun Pavilion, Harrogate, at any time after 2 p.m. on Monday, June 27, except in the case of Representatives and Members of Council, whose tickets will be issued at the A.R.M. Inquiry Office, Royal Hall, Harrogate, between June 24 and 27.

TICKETS

Tickets for functions other than excursions may not be reserved in advance but will be obtained at the Reception Office, Sun Pavilion, Valley Gardens, at the time of the meeting, as in former years.

Tickets for entertainments and receptions to be held on Tuesday and Wednesday will be issued at the Reception Office from Monday, June 27, at 2 p.m.

Tickets for functions on Thursday and Friday will not be obtainable before Wednesday morning.

Note: Representatives and Members of Council should apply at the A.R.M. Inquiry Office, Royal Hall, for tickets up to Wednesday evening.

Tickets for Ladies' Functions will be issued at the Ladies' Club, Prospect Hotel, from Friday, June 24.

BADGES

Members will not be admitted to the Scientific Sections unless wearing badges. They should therefore make a point

**The short morning and evening excursions may also be booked at the time of the meeting at Harrogate.*

of being at the Reception Office, Sun Pavilion, Valley Gardens, by 9.45 a.m. on the first day of their attendance at the Annual Meeting in order to register and obtain their handbook, badge, registration card, and tickets.

Officers of Scientific Sections should inquire for special badges at the Reception Office.

LUNCHEON RESERVATIONS

Non-resident members attending the Scientific Sections are invited to write to the hotel concerned, if they wish to reserve their luncheon in advance. Luncheon reservations may also be made at the hotel before 10.30 a.m. on the day in question.

SPORTS FACILITIES

Golf.—All particulars about the Golf Competitions may be obtained from the Golf Secretary, Reception Office, Sun Pavilion, Valley Gardens, and from the Ladies' Golf Secretary, Ladies' Club, Prospect Hotel.

Other Sports.—Facilities for tennis, putting, miniature golf, bowls, riding, and boating are also available.

Bridge.—Arrangements have also been made for bridge to be played at the Stray Bridge Club, 11, South Park Road, at certain times.

CAR PARKS

Windscreens labels can be obtained by members at the Reception Office, Sun Pavilion, Valley Gardens.

By kind permission of the Director, the Grand Hotel Car Park, Cornwall Road, will be available for the use of members attending the Reception Office and Exhibition.

Municipal car parks are available at: Harlow Moor Drive, Valley Drive, Princes Square, Railway Station, "Belvedere," Victoria Avenue, and the Royal Hall.

The address of the Paddington Group Hospital Management Committee is now: Paddington Hospital, 285, Harrow Road, London, W.9.

BRITISH MEDICAL ASSOCIATION

ANNUAL REPRESENTATIVE MEETING

MOTIONS AND AMENDMENTS FROM DIVISIONS AND BRANCHES

CONSULTANTS AND SPECIALISTS

Domiciliary Visits in Nursing-homes

Motion by BRISTOL: That this meeting regrets that the Minister of Health has set up regulations which make a patient in a nursing-home both private and Service at the same time, and demands that this anomaly be resolved by allowing for all N.H.S. patients in nursing-homes either domiciliary visits by specialists or the charging of fees by their general practitioners.

Motion by CITY OF EDINBURGH: That the recommendation of the committee in relation to domiciliary visits in nursing-homes (para. 71 of Annual Report) should be extended to include all urgent medical or surgical or other cases.

Economy in Hospital Management

Motion by MID-ESSEX DIVISION: That economy in hospital management be effected, first, by a reduction in the administrative costs.

Domiciliary Consultations

Motion by CHELSEA AND FULHAM: That a list of specialists willing to undertake domiciliary consultations should be circulated to general practitioners without further delay.

Proposed Terms and Conditions of Service of Hospital Medical Staff

Motion by CLEVELAND: That all grades of practitioners be paid in retrospect when final terms are agreed and that a no detriment clause be added.

Selection of Specialists

Motion by SOUTH-WEST WALES: That this meeting instructs the Council to take immediate steps to urge the Minister of Health so to amend the Acts or regulations that regional grading committees shall by statute consult the medical practitioners of all classes, general practitioner or otherwise, on the merits of individual applicants for grading.

Motion by SOUTH-WEST WALES: That this meeting instructs the Council to take immediate steps to urge the Minister of Health so to amend the Act that specialists dissatisfied by the decisions of regional grading committees may have the right of appeal to independent appeal tribunals.

Motion by CLEVELAND: That this meeting strongly refutes the suggestion contained in the Regional Hospital Board's circular (49) 70 that the profession has agreed that in the case of regrading on appeal it will be satisfied that payment at the higher grade shall be applied from the date of regrading only.

PRIVATE PRACTICE

Allowances to Medical Witnesses in Criminal Cases

Motion by SOUTH-EAST ESSEX: That (with reference to para. 83 of the Annual Report of Council), in the opinion of this meeting, regulations under which maximum allowances are quoted, but not minimum, lead to inequalities of remuneration for similar services and are most unsatisfactory; and that the Council be pressed to approach the Home Office with a view to a fixed scale of fees being laid down.

Fees for First-aid Lectures

Motion by MARYLEBONE: That with reference to para. 85 of Council's Report the attention of the British Red Cross Society, the St. John Ambulance Association, and the Home Office be called to Minute 89 passed at the A.R.M. at Cambridge regarding fees for first-aid lectures and examinations, etc.

Reports to Insurance Companies

Motion by GATESHEAD: That this meeting reaffirms the resolution of the A.R.M., 1937, with regard to the payment for reports to insurance companies furnished after the death of patients who have been accepted for insurance without medical examination.

Routine Medical Examination of Nurses

Motion by DERBY: That Council be instructed to press for the payment of fees to practitioners engaged in the routine medical examination of nurses.

Midwives Act—Fees for Attendances and Post-natal Examinations

Amendment by DERBY: That the period during which claims for fees under the Midwives Act may be submitted be extended to six months.

Institutional Maternity Services

Motion by NORWICH: That this meeting urges that steps be taken to ensure that local authorities may run institutional maternity services independently of the regional hospital boards, to which general practitioners shall have access.

Position of the School Medical Officer

Motion by BRISTOL: That a school medical officer should send any child he considers to need hospital treatment to the family doctor; he should not, except in case of urgency, send the child to any particular hospital or to any particular consultant, the choice of which is the proper province of the family doctor in conjunction with the parents.

MEDICAL ETHICS

Motion by KENSINGTON AND HAMMERSMITH: That the pamphlet on Medical Ethics be issued not only to those newly qualified practitioners, but also to all overseas practitioners who have arrived into the country during the last ten years, and also be made available to all others who wish to apply for it.

ORGANIZATION

Constitution of Central Council of the Association

Amendment by GLOUCESTERSHIRE: That Section 124 of Council's Annual Report and Section (viii) of Appendix IV to that Report be referred back to Council for further consideration.

Amendment by BOURNEMOUTH: That the proposals for the reconstitution of the Council be referred back for further consideration.

Amendment by BRADFORD: That instead of 10 members of Council being elected by the Representative Body and 37 direct as proposed by the Council, 47 should be elected direct and none by the Representative Body.

Amendment by BOURNEMOUTH: That the Representative Body approve the principle that the number of members of Council directly elected by members in the Branches and Divisions of the Association in Great Britain and Northern Ireland should be increased, provided that in so doing the number of members of Council elected by the Representative Body is not diminished.

Amendment by WINCHESTER: That the Representative Body approve the principle that the number of members of Council directly elected by members in the Branches and Divisions of the Association in Great Britain and Northern Ireland should be increased; that members should be elected by reconstituted Branches, and should be responsible to their Branch.

Amendment by WINCHESTER: That the number of members of Council elected by Branches in Great Britain and Northern Ireland should be increased from 37 to 53.

Amendment by BURY: That the number of members of the Council elected by Branches should not be fewer than 42, and that these 42 or more be distributed among groups according to membership and strength.

Grouping for Direct Election of 37 Members of Council

Amendment by EAST YORKSHIRE: That the Representative Body gives provisional approval to the plan submitted by the Council for the grouping for election of 37 members of Council, but refers the matter for further consideration by the Council, in order that anomalies in the grouping may be reviewed.

Amendment by BOURNEMOUTH: That the Dorset and West Hants Branch be grouped with the Wiltshire, Somerset, and Gloucestershire Branches.

Election of Members of Council by Representative Body

Amendment by WINCHESTER That the direct election of members by the Representative Body should be discontinued. Instead, Council may co-opt up to six members of the Association who are of proved experience and knowledge in the medico-political field, and not representing any given area, and that the chairmen of the Scottish, Welsh and Northern Ireland Committees should be members of the Council.

Amendment by PLYMOUTH That only eight members of Council be elected by the Representative Body as a whole.

Members Ex officio of the Council

Motion: That the following Recommendation of the Council be adopted—That the following cease to be members, *ex officio* of the Council: (a) Immediate Past Chairman of Representative Body, (b) Deputy Chairman of Representative Body and (c) Immediate Past-Treasurer.

Amendment by WINCHESTER That the recommendation be adopted, subject to the addition of the following words: "President-Elect and the Immediate Past President."

Motion by BURY That the term of membership of the *ex-officio* members of Council be limited to three years.

Overseas Members of Council

Amendment by WINCHESTER That the number of members elected by Branches of the Association not in Great Britain or Northern Ireland should be reduced from eight to one—viz., the chairman of the Colonies and Dependencies Committee.

Service Members on the Council

Amendment by WINCHESTER That the present arrangement under which three members of the Council are elected to represent respectively the Royal Naval Medical Service, the Army Medical Service, and the Royal Air Force Medical Service be discontinued, and that the chairman of the Armed Forces Committee be a member of the Council.

Representation of Public Health Service on the Council

Amendment by WINCHESTER That the existing arrangement under which two members of Council are elected by Public Health Service members be discontinued, and that the chairman of the Public Health Committee be a member of the Council.

Representation of Women Members on the Council

Amendment by WINCHESTER That the present arrangement under which women members of the Association elect one member to the Council be discontinued.

The "Six-year Rule"

Amendment by DERBY That membership to the Council for those members elected by Group Branches or Divisions should be for a period of three years.

Agenda of Representative Meetings

Motion by MARYLEBONE That with reference to para 205 of the Council's report Representatives whose motions and amendments have been "grouped" or "held covered" shall be given at least 48 hours' notice in writing, and on the day of the Representative Meeting shall be given the opportunity to meet for discussion in an adjacent room to decide on the proposer of motion, who would be allowed to speak to 10 minutes and reply for 10 minutes, other speakers being limited to 5 minutes. No resolution "grouped" or "held covered" should be taken until one hour after the meeting starts.

Motion by WINCHESTER That Divisions shall submit their resolutions initially to Branch Councils, who, whilst having no power of veto, shall discuss these, correlate them, and forward to an Agenda Committee of the Representative Body. Notwithstanding this, a Division shall always retain the power of forwarding a resolution direct to the Representative Body if dissatisfied with the action of the Branch Council.

Motion by MID-CHESHIRE That the Representatives of the A.R.M. strongly urge the early institution of a "steering committee" for the agenda at Representative Meetings.

Regional Organization

Motion by Winchester: That the primary duty of each Regional Secretary shall be to his Region. He shall pay regular visits to Divisions and be available, in liaison with Divisional Secretaries, for consultation with and visits to individual members, but he shall have access to all central committees.

Position of Autonomous Bodies

Motion by BOURNEMOUTH That the Council be asked to appoint a special committee to consider and report on the situation created by the formation of autonomous bodies within the Association and their relationship to the Representative Body.

Amendment by BROMLEY That so long as the General Medical Services Committee and the Central Consultants and Specialists Committee are autonomous, the Representative Body can no longer be considered to be the Body that formulates the policy of the B.M.A.

That this situation strikes at the whole structure of the Association, and that steps should be taken to remedy it.

Organization of the Association in the Dominions, Colonies, and Dependencies

Motion by MARYLEBONE and PLYMOUTH That a Special Committee be appointed to consider the B.M.A. Overseas organization, including the Dominions, Colonies, and Dependencies, and to ascertain the feelings of all sections of their medical practitioners and others interested.

Quorum of Representative Meetings

Motion by READING: That this meeting considers that the quorum of the Representative Body should be reduced from one half to one quarter of the members elected to attend.

Duties of Representatives

Motion by LOTHIAN: That this meeting, being aware of the confusion which exists as to the duties of a representative, affirms its belief that representatives should be guided by Divisional opinion, but at the same time should be free to make decisions in the light of debates, and requests the Council to make this clear in the Annual Handbook.

Expenses of Representatives Attending Representative Meetings

Motion by SOUTHAMPTON: That in the event of the Council's recommendation in para 116 of the Annual Report of Council being carried (*re* subscription), the expenses of Representatives attending Representative Meetings be defrayed by the Association.

Recognition of Outstanding Services

Motion by GREENWICH and DEPTFORD That this meeting recommends that the Council consider ways in which Divisions could honour members who have rendered outstanding services on their behalf.

NATIONAL FORMULARY

Motion by HENDON. That the Representative Body is of opinion that, while a National Formulary is desirable, early steps should be taken to improve the contents and scope of the existing National Formulary so that it will prove to be of real value to those engaged in the science and art of medicine and to the public at large.

AMENDING BILL

Motion by HENDON That in the opinion of the Representative Body the Minister of Health is primarily guilty of a breach of faith in failing to redeem his promise to provide Compulsory Arbitration for the ultimate settlement of any dispute relating to the remuneration of public practitioners, and secondly of introducing an amending Bill without affording the representatives of the profession a prior opportunity to peruse and comment on its provisions.

Motion by BRIGHTON That this meeting is of opinion that arbitration provided for in the amending Bill should be under Whitley Council, and not as set out in Section 12 of the Bill.

Motion by CLEVELAND: That the profession *insist* on the right to arbitrate from the findings of the Whitely Council.

Motion by BRIGHTON: That this meeting registers its profound dissatisfaction at the Minister's breach of faith in not honouring his undertaking to consult the medical profession before presenting the amending Bill to Parliament.

LAY CONTROL OF MEDICINE

Motion by BISHOP AUCKLAND: That this meeting views with great alarm the threatened lay control of Medicine and recommends that appropriate action be taken.

REMUNERATION OF GENERAL PRACTITIONERS

Motion by BRIGHTON: In view of the failure of the Minister to give a satisfactory reply to the profession's reasoned case for an increase in remuneration, based upon the betterment factor, the Council be instructed to ask local medical committees to invite general practitioners to place their resignations at the disposal of such committees, unless terms acceptable to the majority of the profession are received before Sept. 30, 1949.

Motion by CAMBERWELL: That subject to the receipt of extra grants from the Treasury, this Meeting agrees that the capitation fee for the first 1,000 patients should be raised.

Motion by WEMBLEY: That this Meeting considers that the amount of the capitation fee is not equitable throughout the country and should be made uniform irrespective of area and irrespective of other payments such as mileage and dispensing.

Motion by CLEVELAND: That this meeting wishes strongly to support any action the Council should decide to take under para. 178 of the Report of Council.

TEMPORARY RESIDENTS

Motion by HEXHAM: That the fee of 15s. for attending residents is totally inadequate and compares unfavourably with the pre-1938 P.A.C. remuneration. As this especially affects doctors practising in seaside and holiday resorts where the patients only call in medical aid in cases of severe disability, it is considered that the fee for temporary residents should be not less than one guinea.

BASIC SALARIES

Motion by HENDON: That the Council be instructed to represent to the Ministry of Health that all basic salaries granted by executive councils should be a primary charge on the central pool.

VACCINATION AND IMMUNIZATION

Motion by HENDON: That this meeting is definitely of opinion that immunization and vaccination should fall outside the scope of the contract for public practitioners and be made the subject of separate remuneration both for the services and the reports involved.

PROVISION OF MEDICINES AND APPLIANCES FOR PRIVATE PATIENTS

Motion by HENDON: That disappointment and resentment be expressed by the Representative Body at the failure of the Minister to include in the amending Bill provision for the free supply of medicines and scheduled appliances to private patients.

GENERAL PRACTITIONERS AND SPECIAL DEPARTMENTS OF HOSPITALS

Motion by EAST HERTS: That the maintenance of pathological and radiological facilities for general practitioners without the intervention of a consultant in a hospital out-patient department is essential.

MEDICAL SERVICES COMMITTEE PROCEDURE

Motion by HENDON: That the Council be urged to make early representations to the Minister to have the regulations relating to the procedure of the medical services committees amended to bring them into line with those applicable to Northern Ireland, whereby a defendant doctor appearing before a medical service committee may have, if he so desires, services of a paid advocate or solicitor.

GENERAL PRACTITIONERS AND HOSPITAL WORK

Motion by MID-CHESHIRE: That this meeting protest strongly against the steady exclusion of general practitioners from work in hospitals.

Motion by EAST HERTS: That the apparent policy of the regional boards to eliminate general practitioners from hospital work is to be deprecated.

DECISIONS OF MEDICAL PRACTICES COMMITTEE

Motion by LIVERPOOL: That wherever the decision of the medical practices committee differs from that of the local executive committee, the medical practices committee should furnish in writing to the said executive committee the reasons for its decision.

EMERGENCY DISPENSING

Motion by WEMBLEY: That this meeting considers that the payment of 2s. 6d. per 100 patients for emergency dispensing is ludicrous and quite inadequate; that steps should be taken immediately in England and Wales to adopt the procedure E.C.10A as in Scotland.

MEDICAL ADVISORY COMMITTEES

Motion by NEWCASTLE-UPON-TYNE: That as medical representation on boards and committees of the National Health Service is inadequate, the Association be instructed to press for either direct representation of appropriate sections of the profession on these boards and committees or that medical practitioners be appointed to boards and committees after consultation and in agreement with such sections of the profession.

A B.M.A. CAR BADGE

Motion by HENDON: That the Representative Body compliments the Council on the design of a car badge prepared in response to the appropriate resolution last year and restates its view that the badge should be made available forthwith to members of the Association.

Motion by CITY: That this meeting considers the sign "Doctor" on motor-cars is now unnecessary and undesirable.

MEDICAL OFFICERS OF APPROVED SCHOOLS

Motion by NEWCASTLE-UPON-TYNE: That this meeting considers that the rate of salary offered to medical officers of approved schools is totally inadequate considering the nature and amount of work entailed and that this present arrangement should not be accepted.

DOCTORS' CARS

Motion by NEWCASTLE-UPON-TYNE: That this meeting is not satisfied that the profession receives a sufficient measure of priority in the delivery of new cars.

SALARIES IN THE PUBLIC HEALTH SERVICE

Motion by WEMBLEY: That this meeting considers that the attention of the profession as a whole should be drawn to the undesirability of medical practitioners accepting service with local authorities on a sessional basis which would tend to enable such authorities to carry out their public health work and thus ignore the British Medical Association's conditions of service for whole-time public health officers.

MEMBERSHIP SUBSCRIPTION

Amendment by CARDIFF: That the subscription of medical officers in the public health service who receive no income tax allowances in respect thereof should remain as at present.

Motion by SOUTH ESSEX: That this meeting requests Council to introduce a scheme whereby a member can commute his annual subscription to a lump sum life subscription.

ENTRIES IN TELEPHONE DIRECTORIES

Amendment by CLEVELAND: That this meeting does not agree with para. 119 of the report since the addition of the specialty

is the only method of distinction where names are similar, as occurs in this area.

MEDICAL PRACTITIONERS HANDBOOK

Motion by HENDON: That this meeting urges the Council to take steps for the preparation and early issue of a Newly Qualified Practitioners Handbook.

APATHY OF THE PROFESSION

Motion by BRIGHTON: That the Annual Representative Meeting views with profound regret the apparent apathy in the profession, and instructs the Council to use the editorials of the *British Medical Journal* as much as possible to rouse members of the profession to realize their responsibilities in the outcome of the present conflict.

MEMBER OF U.S. ARMY AIR FORCE MEDICAL CORPS

Motion by Metropolitan Counties Branch: That all members of the United States Army Air Force Medical Corps be elected honorary members of the Association for the term of their service in the United Kingdom.

PAYMENT OF MILEAGE TO MEMBERS ATTENDING MEETINGS

Motion by LANARKSHIRE: That it be remitted to the Council to consider the question of introducing the payment of mileage at the usually accepted rates to members attending B.M.A. committees of Divisions and Branches and also certain central committees where the payment of a mileage grant could be regarded as both appropriate and equitable.

HEALTH CENTRES

Motion by HENDON: That the Representative Body is of opinion that a doctor practising in and from a health centre should not be obliged to enter into partnership with any or all of his colleagues who may be similarly placed.

Motion by CITY: That this meeting whilst approving in principle the idea of health centres views with alarm the attitude of local health authorities in attempting to obtain the acquiescence of local practitioners in the establishment of such centres without definite terms of service being previously laid down and calls upon the Council to open immediate discussions with the Minister of Health.

OTHER MOTIONS BY DIVISIONS AND BRANCHES

Motion by TORQUAY: Believing that decisions backed by the Association as a whole must carry greater weight with the Minister and with the public than decisions of individual groups and with a view to maintaining the unity of the profession, an opportunity should be given to the Groups to correlate their views one with another and with the policy of the Association as a whole before any decisions on policy are made known to the Minister or the Press.

Motion by TORQUAY: That, in order that the Association should become a potent instrument in obtaining satisfaction, the Council should bend all their energies in the coming year to arming the Association with the necessary power to enforce their demands.

Motion by BRADFORD: That in the opinion of this meeting the only organization which can protect the interests of the general practitioner is one holding the certificate of the Registrar of Friendly Societies.

Motion by BROMLEY: That the meetings of the Representative Body should be recorded verbatim as in *Hansard*, and should be available for reference.

Motion by LANARKSHIRE: That in view of the introduction of the National Health Service and the possibility of war in the future, the interests of practitioners called for service with the Forces be safeguarded by the following measures:

(a) Where service pay is less than the net income, earned under the National Health Service, the difference to be made up from the total sum available for payment of practitioners under the National Health Service.

(b) That on return from service, a practitioner's income be maintained for a period of eighteen months at the gross rate earned prior to service.

Correction

In the form of contract for whole-time consultants or S.H.M.O.s (*Supplement*, June 11, p. 320) the Ministry mistakenly included an asterisk after the words "their temporary absence."

PRACTICE OF ORTHOPTICS

The Council of the Faculty of Ophthalmologists has issued a memorandum on orthoptics. The report was originally drafted by the Orthoptic Board and has been modified by the Council of the Faculty. It has been sent to the Ministry of Health and the British Optical Association.

The memorandum, here slightly abridged, begins by distinguishing two classes of people doing orthoptic work.

(1) *Orthoptists*, who are medical auxiliaries and hold the Diploma of the Orthoptic Board (D.B.O.). Their training and work are under the direction of recognized medically qualified ophthalmologists.

The course of training occupies two years (full-time) and is carried out in orthoptic schools recognized by the Orthoptic Board. Holders of the diploma are entitled to practise orthoptics, but they must abide by the ethical rules of the British Orthoptic Board, which forbid those who hold the diploma to prescribe glasses or to treat cases other than those referred to them by recognized ophthalmologists. These orthoptists work in orthoptic departments of ophthalmic hospitals, in ophthalmic departments of general hospitals, at school ophthalmic clinics, or in private practice. They are mostly women. There are about 241 orthoptists holding the D.B.O. practising in this country. The examination for the diploma was started in 1935.

(2) *Ophthalmic opticians who have special knowledge of orthoptics* are for the most part those who hold the Diploma of Orthoptics (D.Orth.), which is granted by the British Optical Association (B.O.A.). Their training and work are not under the direction of the medical profession.

The examination for the D.Orth. is open to members of the B.O.A. or to holders of any qualification in refraction or optometry approved by the Council of the B.O.A. There is no prescribed course for the D.Orth., but nearly all those who take the examination study at either the Refraction "Hospital" London or at the Manchester College of Technology. (They usually attend only once a week for a year.) These optician-orthoptists work for large firms of opticians, or on their own, in which case orthoptics is usually a sideline, their main work being refraction. There are about 250 ophthalmic opticians in this country who hold this diploma. The examination for the D.Orth. started in 1939.

At present there is a shortage of orthoptists, partly because fewer were trained during the war, and partly because of the increased demand for orthoptic work. More students are now being trained. When the school ophthalmic clinics come under the Hospital Service more orthoptists will probably be required. It is estimated that some 600 orthoptists will soon be needed in the final Ophthalmic Service. The memorandum assumes that the staff of all National Health Ophthalmic Clinics will consist of one or more of the following: ophthalmic surgeon, refractionist, orthoptist, and dispensing optician.

The limited practical training available for the candidates for the D.Orth. has been considered. The amount of properly selected clinical material available for teaching is negligible compared with what is available through the orthoptic schools attached to hospitals. Optician-orthoptists are handicapped in their work by lack of opportunity of association with ophthalmic surgeons. The authors of the memorandum consider that, since the ophthalmic surgeon is ultimately responsible for the patient, if holders of the D.Orth. are to be employed in the Health Service as orthoptists they should be so only after they have had the opportunity of working with ophthalmic surgeons and of undergoing a course of training in the recognized orthoptic school of a hospital.

DOMICILIARY SPECIALIST SERVICES

A woman confined in a private maternity home may be visited by an obstetrician or her baby by a paediatrician under the domiciliary specialist service in an emergency. The Minister has decided that such cases fall within the scope of the specialist domiciliary service when specialist attention is needed and when medical considerations make it impossible for the patient to be removed to hospital.

Correspondence

Trainee Specialists

SIR,—You have had a number of letters recently regarding the proposed terms of service for trainee specialists, but we should like the views described below to be given some further publicity.

We are concerned that in the proposed terms of service no allowance has been made for seniority lost due to service with H.M. Forces. We understand that the Spens Committee was guided, among other principles, by the principle that placing on the scale should have regard to age. The committee's report was accepted in principle by the Ministry of Health, but in the proposed terms of the Ministry of Health no allowance has been made for the ex-Service trainee specialist who, after one to six years in the Services and at a considerably older age, will receive a salary appropriate to a much younger person qualified for a short time—e.g., a Class II post holder will receive £700 on the Spens scale (£775 on the Ministry of Health scale). This is thought by the Spens Committee to be adequate for a person aged 26. This salary spells dire hardship for an ex-Service trainee of, say, the age of 30, for which age the Spens Committee regard £1,100 as being essential to avoid hardship.

To avoid serious injustice we submit that in arriving at the appropriate salary on this scale for trainee specialists allowance should be made for the number of years served in H.M. Forces. This principle has already been conceded in the case of specialists, where the conditions are exactly comparable. The scales are fair to the newly qualified trainee, they are fair to the specialists, they must also be fair to the ex-Service trainee specialist.

Since July 5, 1948, many ex-Service registrars have had their posts converted into a permanent hospital appointment. We submit that all holders of registrarships held under the further-education scheme should qualify for retrospective payment to July 5, 1948.

We appreciate that it would be difficult for individual hospitals to meet all these requirements out of their present estimates. We submit, therefore, that central action on the part of the Ministry of Health should be taken in all these individual cases until the situation has rectified itself.—We are, etc.,

J. G. HOWELLS.
J. T. HUTCHINSON.
D. V. MARTIN.
D. S. MACPHAIL.

P. SAINSBURY.
R. F. HOBSON.
E. J. ANTHONY.

SIR,—I have been waiting for some time for a protest to be made in your columns about the remuneration for trainee specialists which has been proposed by the Minister. I appear to have waited so far in vain.

The salary proposed by the Spens Committee for a Grade III trainee specialist was £600 p.a. (living out). Mr. Bevan proposes that this should now be £670 p.a.—an increase, even when the Government superannuation contribution has been added, of only about 20.5% to allow for the betterment factor. At a time when Ministry of Labour figures show that the average wage-earner is getting 120% or more than he did in 1939 the young trainee specialist is to get 20.5% more than the Spens Report said he should have got in that year. In other words, the working-class betterment factor is to be 120 or more; the betterment factor of a registrar is to be 20.5. This makes complete nonsense of the Spens Report.

Furthermore, while it is bad enough for the overworked general practitioner to get only 34% gross, it is still worse for the registrar, often with a wife and family to support. The latter gets a betterment of only 20.5% net and is far nearer the subsistence level. Many of these people, whose only sin is that they love their work and wish to take a higher qualification in it, are living on the verge of bankruptcy, with an ever-increasing overdraft to distract them from their work.

So far, however, the British Medical Association has done absolutely nothing to remedy this state of affairs and to remove this gross injustice, or if action has been taken it has been done behind closed doors. Let us therefore demand with a united

voice that the strongest protest be made to the Ministry in order that this arrant piece of injustice may be removed at the earliest opportunity. It is high time that the Minister was told with no uncertain voice that "what is sauce for the gander is sauce for the goose."—I am, etc.,

Poole, Dorset.

A. ARNAUD REID.

Terms for Consultants

SIR,—I believe the comments on the proposed terms of service for hospital staffs (*Supplement*, March 19, p. 147) are misleading in regard to superannuation. They suggest that the employer's 8% contribution is to be deducted from a betterment factor of 20%—in other words, that it may be considered as a part of the employee's remuneration, as it is a payment made on his behalf. This is not so. Also it is clear that superannuation and betterment are separate problems: it is unfortunate that they have arisen simultaneously.

The employer's 8% superannuation contribution is not made on behalf of the employee: it is made by the employer, and he receives benefit from it. It gives him the right to retire an employee who, though he has given long and faithful service, has ceased to be useful through old age or infirmity. The pension avoids hard feelings and recriminations. Similarly the employer, by having paid superannuation contributions, can feel that he has honourably discharged his responsibilities to the widow and family of a deceased employee. Where there is no scheme to which he can contribute the employer himself has an obligation to provide a pension for his ex-employee.

Of course the employee also has a duty to provide for his old age and for his family in event of infirmity or death. Responsibility in this matter of pension is divided between employer and employee. The fact is recognized and regularized in superannuation schemes.

Your suggestion is tantamount to supposing that, if a man earning £1,080 p.a. entered a (similar) superannuation scheme, his salary would be reduced by £80 p.a. to cover the employer's contribution.

There are only two explanations of the proposed terms: either the remuneration is being reduced to meet the Government's superannuation contribution, or the Minister is offering us a betterment factor of 11%.—I am, etc.,

Preston.

J. A. CARR.

Specialist Grading

SIR,—The main line of demarcation in the grading of specialists should be between (1) men whose income is solely derived from consultant practice, and (2) men whose income is partly derived from general practice, although also engaged in some specialty. The first group could be divided into two categories, giving the following classification:

1. *Staff Specialist*.—Doing consultant work only; holding a postgraduate qualification; having been in consultant practice at least five years.

2. *Associate Specialist*.—Doing consultant work only; holding a postgraduate qualification; having been in consultant practice less than five years. Automatic promotion to staff specialist after completing five years of consultant practice.

3. *Senior Hospital Medical Officer*.—Engaged in general practice but doing some specialist work; postgraduate qualification not essential; promotion to associate specialist when he fulfils the necessary criteria.

The remuneration of the first two groups should be at a considerably higher level than for the S.H.M.O. group, as the latter can rely chiefly or partly on income from general practice.

Precise definitions such as the above should be agreed with the Ministry before appeals are due to be heard by the Appeals Committees.—I am, etc.,

Blackpool.

R. E. HORSFALL.

SIR,—Mr. R. L. Newell (*Proceedings of Council, Supplement*, May 21, p. 283) stated that grading committees decided entirely on the basis of a man's qualifications. My personal experience refutes his assertion and supports the views and warnings put forward by the Secretary (*Supplement*, May 14, p. 269) with regard to the senior hospital medical officer grade.

I am over 12 years qualified, and in January last I filled up a form sent to me for specialist grading. Having heard nothing

meanwhile, I recently obtained a personal interview with my regional board and was then told that, of the people who by postgraduate degrees, experience, etc., were of specialist standard, not more than 50% would be graded full specialist, and of the people of assistant specialist standard the majority would be graded as senior hospital officers. Furthermore, at this interview I was enlightened as to the reason for this policy. The object was to save money by down-grading as many people as possible.

When I tried to find out, at the interview and subsequently, who or what body had the privilege of deciding my grading and future I was met by a smoke-screen. The decisions are apparently being carried out in secrecy behind closed doors. The secrecy is not quite complete, because some people in a position to "work behind the scenes" or "in the know" have already been told that they will be graded full specialists.—I am, etc.,

M.D., M.R.C.P

Disparity in Incomes

SIR,—I enclose a cutting from the *Sunday Express* of April 17 quoting figures for the West Ham area which, if correct, should be more forcibly brought to the notice of the public. Analysis reveals the following average incomes during the first nine months of the Health Service: Doctors, £736, dentists, £2,942; chemists, £2,413.

Such figures show a sorry state of affairs the G.P.—the very hub of the Service—finds himself the poor man of the show. His more fortunate colleagues can "shut shop" and forget their patients and customers during their leisure hours, and feel satisfied that they receive payment for what they have actually done during working hours.

Fundamentally, the medical practitioner should be the highest paid of the professions in the Service. His training is longer and more exacting, and he carries by far the greatest responsibility. Unfortunately he has had no business experience and now finds himself sadly lacking in the fight for financial existence, without which he cannot hope to maintain his professional dignity.—I am, etc.,

Wallasey, Cheshire.

THOS. H. H. GREEN.

Allowances for Professional Witnesses

SIR,—There will be many of your readers who have been annoyed to find that they are not eligible for payment of a professional-witness allowance for attending the Criminal Courts to give professional evidence in accordance with the scales recently defined in the Witnesses Allowances Regulations, 1948 (Statutory Instrument No. 1909 (L.23)), as published in the *Supplement*, Sept. 25, 1948 (p. 129).

The reason for this refusal by the Courts to pay such witness fees is that the Home Office issued a circular on Aug. 26, 1948, to all Clerks of the Peace, Clerks of Assize, and Clerks to Justices, giving guidance in the implementation of the Witnesses Allowances Regulations which came into operation on Sept. 13, 1948. This circular stated that professional witnesses' allowances should not be paid to salaried officers who did not lose remuneration by reason of attending court, with the result that professional-witness fees have been refused to many doctors working in whole-time salaried posts (in hospitals and other public health services, etc.), to their great indignation.

My Society was concerned about this position and took Counsel's opinion with regard to the validity of the Home Office circular, which, unlike the regulations, had not statutory force. Counsel advised that paragraphs 2 and 5 of the Home Office circular appeared to be conflicting.

The Home Office appear to concede in paragraph 2 that a witness specifically called in, because of his expert and professional qualification, may be given an appropriate allowance. In paragraph 5 they exclude salaried officers without giving any indication that the court ought to take into consideration whether or not the giving of evidence may fairly be regarded as incidental to the officer's ordinary duties, and whether trouble or loss of time has been occasioned.

The Society made representation to the Home Office requesting that the circular should be revised, but was informed that the Home Secretary would not be prepared to depart from the statement in his circular that professional-witness allowances should not be paid to salaried officers. It was accordingly

decided to seek the ruling of a High Court judge on the proper construction of the "Costs in Criminal Cases Act, 1900," and the "Witnesses Allowances Regulations, 1948," on the following grounds.

Subject to the regulations, there may be allowed such sums as appear to the court reasonably sufficient to compensate the witness for the expenses, trouble, or loss of time properly incurred in or incidental to the giving of evidence. It is the duty of the Taxing Officer to "ascertain the amount" of costs which the court has directed to be paid out of public funds. In the ordinary way the Taxing Officer ascertains the amount without reference to the court, and he has been guided by the instructions contained in the Home Office circular. Accordingly, the refusal by a Taxing Officer of an appropriate allowance to a hospital doctor who was salaried and lost no remuneration by attending court, on the grounds that such an allowance conflicted with the directions in the Home Office circular, was recently challenged, and it was contended that the particular witness had not been compensated for trouble or loss of time which attendance at court necessarily involved.

An application for the reconsideration of the fees to be allowed in this case and for a ruling on the principle to be applied was heard by Mr. Justice Devlin in Chambers. It was argued that paragraph 5 of the Home Office circular was too narrow, as, if the doctor had been an ordinary general practitioner, he would have incurred the expense of having to employ the services of another doctor to attend to his patients during the time he was absent at court, or, if he did not adopt this course, he would have to see his patients in time which he might otherwise have devoted to leisure.

Mr. Justice Devlin agreed with this contention and stated that he would direct the Clerk of Assize that the directions in paragraph 5 of the Home Office circular (*re* professional-witness fees to salaried officers) were too narrow, and the mere fact that a practising doctor does not lose income is not sufficient to reduce him to the status of an ordinary witness. He further stated that it was for the Clerk of Assize to assess what amount should be paid for the trouble and loss of time.

It is suggested, therefore, that salaried doctors who find themselves in a similar position of having been refused a professional-witness allowance in accordance with the scale described in the Witnesses Allowances Regulations, 1948, should argue the point whenever it arises, and should appeal to the judge or chairman of the court if the Taxing Officer refuses the appropriate allowance, making use of the opinion expressed by Mr. Justice Devlin as described above.

This legal ruling will be brought to the notice of the Home Office, and it is hoped that the offending paragraph in the circular will be revised.—I am, etc.,

ALISTAIR FRENCH,
Secretary, The Medical Protection Society

Letter from a Division Chairman

SIR,—The letter (*Supplement*, April 30, p. 253) deploring the poor attendances at B.M.A. meetings suggests: "The fourth explanation, and the most reasonable, was that a condition of complete and profound apathy pervaded the bulk of the doctors." But it fails to consider the causes of the apathy. *What are they?*

In my opinion the apathy is due to the belief that whatever resolutions may be passed at the meeting, or in London, no appreciable alteration would be effected. And again *why?* To go back only a short period, it had been said that there were not enough doctors to work the health service, yet when about half voted in its favour the other half were officially advised to join. *Why?* Because those at Headquarters knew that, whatever a local practitioner had signed, few would hesitate to break their word if it were to their financial advantage to do so. One practitioner could not trust another local practitioner to keep his word and not to take advantage of him.

Put shortly, there is a complete lack of confidence. We have been told that ballots were secret to avoid victimization. If a cause is worth while it is worth being made a victim in an endeavour to uphold it. Did the early Christian martyrs complain there was no secret ballot?

The lack of confidence is engendered by lack of truth and experience of the way the Protection of Practices Scheme was

not kept. Privately it was reported that one practitioner in Kent had acquired over 400 panel patients from an absentee practitioner; yet he did not pay into the scheme a single shilling for private cases. Are we really going to believe he had none? But in the official report these facts were not published, nor was his name. Yet public morality is formed by public opinion. The number of unethical and immoral acts that are passed by is prodigious.

Let us face it, there is no faith, for professional, like public, morality is at a low ebb. Until this is altered, there will be apathy. As Sir Stafford Cripps has said, this is more a moral than an economic crisis.—I am, etc.,

Pettwood, Kent

G. C. MILNER.

Senior Hospital Medical Officer

SIR.—The letter from "Mens Sara" (*Supplement*, April 30, p. 260) raises very important points to all young members of the profession on the specialist side—that is, the point of grading, status, and tenure of a post. In the past, when experience was adequate, one obtained an appointment, and if one's ability was worthy the post was permanent. Such is my own lot as radiologist to two hospitals, where I have handled the work with commendation, and salary increment, since appointment. Now the grade of senior hospital medical officer, which did not exist when one entered the Service, is brought forward as a blind alley with meagre salary increments and no visible chance of rapid upgrading. The alternative, non-acceptance, means unemployment—or country-wide "touting" with no settled domicile.

At a recent meeting it was stated that nobody could be accepted as a specialist without two points: (a) Five years' experience in the specialty, and (b) attaining the age of 32—this despite provision for a specialist below 32 in the proposals. We were informed that these were basic grading tenets.

In my own case I have nine months to wait. Whilst it would be aggravating, in view of a dentist's age not being applicable but only ability being the arbiter, it is more than this owing to the strong likelihood that such grading may persist, after one has officially "qualified"; and the amount of responsibility demanded remain constant. Such grading may attach to the post and affect future holders.

The B.M.A. should demand endorsement of a resolution passed at the meeting which I mentioned. It was to the effect that all gradings of senior hospital medical officer should be subject by legislation to yearly review, with a view to the earliest possible upgrading, and that the ranking should not be used as a means of employing cheap specialized labour. The point is vital. At present the seniors are not involved. Apart from to-day's junior ranks being to-morrow's seniors, once this is established its future revocation will be nearly impossible. The slogan should be, as with the T.U.C., "The rate for the job"—especially when one has no other consulting income.—I am, etc.,

BELOW AGE.

SIR.—I am gravely disturbed by the letter from Dr. Stephen Krauss (*Supplement*, May 7, p. 266) on the above topic. His point of view is all the more alarming as "quite a number of colleagues . . . hold these views." In my submission the suggestion that senior hospital officers should be made eligible for distinction awards is completely defeatist in its approach, and is moreover foredoomed to failure.

It appears clear that a considerable number of hospital medical officers who have in the past been regarded as specialists by their colleagues are in danger of being placed in this grading. Surely they should not fight for better remuneration within this grading, but for the right of a really effective appeal against the decision of the Assessment Committee.—I am, etc.,

Birmingham.

F. A. BLEADEN.

Importance of the G.P.

SIR.—It is well that general practitioners should insist on adequate remuneration, for the labourer should be worthy of his hire—should be, although the present form of payment hardly encourages the development of the best kind of service.

But there are other matters even more important than pay which demand consideration by the profession and the public.

I refer to the dignity of and respect for the general practitioner, and for this reason I am distressed at the provision not permitting him to order an arch support, an abdominal belt, and some other simple things for his patients, but must direct the patient to the hospital.

There are other restrictions of the general practitioner's activities which I think are not in the interests of doctor or patient. No facilities have been granted him to have simple pathological and x-ray examinations done at his request without the intervention of the hospital physician or surgeon. I am sure it is all wrong and an insult to a branch of the profession which in Germany produced Koch and here gave us Sir James Mackenzie, to mention only two names.

The importance of the general practitioner—the title of an article I wrote for the *West London Medical Journal*, a copy of which I sent to the Minister of Health—must be recognized if a really satisfactory medical service is our aim. The general practitioner, as I suggested in a memorandum submitted to the conference of universities and Royal Colleges met to consider alterations in the students' medical curriculum, must be trained to play his part.—I am, etc.,

London, W.8

HAROLD H. SANGUINETTI.

Health Centres

SIR.—There has been much discussion over the establishment of so-called health centres under the National Health scheme. I recall that, when the introduction of a National Health Service was advocated, much play was made with the advantages which would accrue from the pursuit and practice of preventive medicine. We were told that under such a scheme the general practitioner would be encouraged to spend much of his time in educating the people in the prevention of illness and in the attainment of positive [sic] health. In what directions have they been so encouraged, what new efforts in the prevention of disease have been initiated? I have heard of none.

On the contrary, local authorities are being enjoined—and some are planning—to erect polyclinics for the treatment of disease. In one of the larger Midland towns plans are afoot for the erection of so-called health centres which are designed to replace the surgeries now provided by the general practitioners. In other words, not health centres but centres for ill-health are being envisaged. The disadvantages of such centralization are too obvious to need elaboration.

My own conception of a health centre—by no means original—is that it is a place devoted, among other things, to:

- (a) The education of the public in all matters relating to the health and well-being of a community—for example, food, housing (including lighting and ventilation), clothing, exercise, work and fatigue, mental and physical rehabilitation.
- (b) Child and mother welfare.
- (c) Mental health.
- (d) The prevention and treatment of endemic diseases, whether communicable or not—e.g., rheumatism, syphilis, tuberculosis, poliomyelitis, diphtheria, and the like.
- (e) The prevention and control of epidemic disease.
- (f) Demography.
- (g) Research.

For a large town only one such centre would be necessary. It should have a central location, be of first-class architectural design, and should exhibit the highest available standards of construction, hygiene, and aesthetics; in fact, it should be a centre of which the community could be as proud as of the town hall, and might form part of a civic centre.

But such a grand design has been allowed to give place to numerous little treatment centres which will afford the public no greater speed or efficiency of treatment except in one or two directions—e.g., x rays and minor surgery. It remains to be seen whether, indeed, general practitioners will avail themselves of these centres, as they will be free to employ them or not as the convenience of their practices directs. It is not unlikely that some of these buildings may come to be white elephants erected and run most uneconomically to the greater glory of no one, except perhaps of the nephelococcygeans who plan them.

There is another consideration: is it expedient that a local or regional public body should acquire a vested interest in ill-health? This will undoubtedly occur if working space in these treatment centres is rented to general practitioners, much in

the same way as landlords in Harley Street have come to demand increasingly exorbitant rentals of specialists. *Caveat emptor!*—I am, etc.,

Elton, Notts.

V. L. FERGUSON.

To Stop Frivolous Calls

SIR,—May I make a suggestion to cut down the cost of the N.H.S.? My idea is that each patient should get free of charge from his local executive council a book of, say, 20 tickets to last a certain period, say six months. Each ticket would represent a service from his doctor, and would be collected by the doctor at each visit or consultation. At the end of each month these tickets would be returned by the practitioner to the local executive council. If the patient exceeds his quota of tickets then he can purchase more at a nominal fee, say 1s. each. By this means no doctor can be accused of making money out of the scheme and it will stop frivolous calls on the doctor's time.—I am, etc.,

Hove, Sussex.

PAUL E. R. KIRBY.

Transfer of Specialists

SIR,—On so many occasions has the Minister of Health broken faith with the professions undertaking service under the Health Act that it is somewhat unusual to find him for once attempting to keep it. What is rather disturbing, however, is to find that in order to maintain this faith the Minister finds it necessary to break the law.

The Ministry of Health has informed hospital boards (we are told) that the Minister has a moral obligation for seeing that displaced members of hospital staffs are given, as far as is practicable, the opportunity of undertaking similar duties elsewhere. Quite apart from the fact that it, being a *moral obligation*, must be somewhat outside the Minister's usual line of country, a perusal of the regulations (which have all the force of law) dealing with the making of hospital appointments reveals that no appointment of a specialist may be made except in accordance with those regulations. Statutory Instrument No. 1416, 1948, sets out the manner by which all specialist appointments shall be made, and para. 8 thereof lays it down that in no other manner may such appointments be made.

Now it would seem that the Minister, putting himself above the law which he himself has made by virtue of the powers vested in him under the Act, has informed hospital boards that they should make appointments in a manner other than that prescribed by the regulations—viz., merely by finding alternative employment for those whose jobs cease to exist for any reason. I suggest that he does not possess the authority to issue such a directive, the terms of which aim to override the provisions of the regulations already laid before Parliament, and I suggest further that no hospital board has any power to act contrary to those regulations, no matter what its master may direct it to do.

The regulations clearly state that they will apply "on the occasion of each vacancy in an office, which for this purpose includes a new office which the board propose to fill." If a specialist's services are dispensed with because the office which he has formerly held ceases to exist he is indeed unfortunate, and it would appear that the Minister really wishes to prevent any such injustice or hardship from arising, but it is equally clear that no hospital board possesses the authority to appoint that specialist to another office without going through the procedure laid down in the regulations cited above, which means advertising the vacancy and setting up the appointments advisory committee, etc. Any appointment made other than in the manner prescribed is liable to be declared invalid in the courts and set aside.

At present every specialist appointment in the country exists under a certain title. The sudden imposition of common ownership of hospitals has not implied necessarily an interchangeability or transferability of the incumbents of specific appointments. The physician in charge of cardiac department in Hospital X, engaged for that purpose and under that title, is not necessarily bound to render services in other hospitals under the same regional board, although there have been recently some appointments which have stipulated that the incumbent's services may be required from time to time in other institutions under the board's control.

Even in the latter case the original appointment is made principally to one hospital, and visits from time to time to other institutions are of a nature subsidiary to the principal appointment. Should that principal appointment cease to exist, could the specialist concerned still be deemed to be in the employ of the hospital board? And could he be transferred to another hospital in the service of the board? It is my suggestion that he could not. It is my further suggestion that such subsidiary duties which arose by virtue of his holding the principal appointment would no longer be open to him, and that they would thereupon require to be carried out by some other specialist still in the employ of the board. Of course much would depend upon the exact nature of the contract which the "displaced" specialist had entered into in the first place.

Take as an example the post of surgeon to the (fictitious) Town of Nod Hospital. That is the appointment which a particular man is assumed to hold. Incidental to this, and because he holds it, he also visits once a week a small cottage hospital near by. The board decides to close the Town of Nod Hospital and make it into a purely orthopaedic centre, appointing to it an orthopaedic surgeon from somewhere else. The general surgeon finds his services are dispensed with, for there are no longer any general surgical beds there.

Several points arise. First, what is his future position at the small cottage hospital near by? He had never actually been appointed to it as a surgeon, his single weekly session there being regarded merely as part of his duties at the main hospital, and being consequential upon his holding that appointment. That, however, is the least important point.

Suppose that, in accordance with the Minister's recent directive to hospital boards, the board offers that specialist an appointment as surgeon at the City of Blanktown Hospital (also fictitious), would such an offer be *intra vires* the regional board, or would the board have to advertise a vacancy on the staff of the City of Blanktown Hospital and then hope that the surgeon in question would be selected to fill it? Could the difficulty be got over by the board's effecting a union between the two hospitals at Nod and Blanktown and regarding them thereafter as one hospital simply divided into two parts, one consisting of the "general" and the other of the "orthopaedic" part of the same hospital?

It might be argued that such a union would validate the transfer on the grounds that the specialist was merely changing the venue of his department within the same single administrative unit—the same hospital, now departmentally divided but still administratively a single hospital. But while such an argument might well validate the transfer in these circumstances it is extremely difficult to find grounds to validate the transfer of a specialist to an altogether different hospital simply in order that he should suffer no hardship because his former office had ceased to exist. The Minister's desire to prevent hardship is one thing. Compliance with the law is another.

To put a man on to the staff of a hospital of which staff he is not at present a member must surely be interpreted as "filling a vacancy," even if that vacancy is being specially created for the express purpose of being filled by that particular man. If this be accepted as a reasonable argument then the regulations cited above must apply in every such case, and it therefore become *ultra vires* any regional board to carry out the undertaking given by the Minister regarding the re-employment of displaced specialists. For the Minister's undertaking to be possible some amendment becomes necessary to the regulations concerned. Failing this amendment the suggestion is offered that any appointments made not in accordance with the terms of the regulations will be invalid, liable to be set aside by the courts; and, moreover, any remuneration paid out by way of salaries in respect of such appointments might even be regarded as the wrongful application of public money.

It is indeed unfair that a specialist be dispensed with because of some matter of policy affecting the office which he holds and may have held for many years, but it is more important that a constant vigilance be maintained to see that both the Minister and his stooges on regional boards and other committees carry out their duties under the Act and administer it strictly in accordance with its provisions and the provisions of the regulations and orders made under it. It may well be that I am in error in my interpretation of the regulations in question, but it appears to me that, before accepting the Minister's general offer of alternative appointment "wherever practicable," the B.M.A. should take advice as to whether it is within the authority of regional boards to act on this Ministerial directive, and if my own suggestions are correct then the sooner an amendment to

regulations to cover such cases is made the better it will be for all concerned. I do not think the question is just academic—I am, etc.,

Penzance Cornwall

GEOFFREY MYERS

POINTS FROM LETTERS

Supply of Glasses

Mr S BLACK, Director, Information Bureau, Association of Optical Practitioners, writes: I think Dr Coke Harvey's letter (*Supplement*, May 7, p 267) on the difficulty of Mr X in getting his spectacles repaired requires some explanation. The N.H.S. regulations demand that a re-examination of the eyes is necessary before a repair can be carried out if more than two years have elapsed since the last test. The reason for this regulation is to discourage patients from allowing too long to elapse between examinations and because it is cheaper in many cases to supply a new frame rather than to patch up an old frame after several years' use. Mr X had four alternative ways open to him to obtain an examination of his eyes. Through the Health Service he could have consulted an ophthalmic medical practitioner, or an ophthalmic optician; or he could have had his eyes examined at an eye hospital, or lastly he could visit an ophthalmologist privately. Apparently Mr X took the last course, and therefore he was not entitled to obtain free spectacles. Health Service spectacles cannot be supplied to a private prescription. If a patient brings a private prescription and insists on having spectacles through the scheme, the optician has to inform him that his only way to do this is to have his eyes examined through the Health Service, when any necessary spectacles can be supplied.

Comparative Incomes

A C E writes: It is indeed surprising to see the apparent apathy of the profession to the cavalier treatment it is receiving from the Minister. I am one of the "haves" with a gross income of over £3,000, but I really wonder how some of our colleagues are managing to pay overheads, let alone live. I was very shocked recently to see our local executive council's position for the first nine months of the N.H.S. Translated into yearly averages it is as follows, in round figures of payments: Average gross payments per doctor, £1,600, per dentist, £4,550, per optician, £3,200, per chemist, £3,000. My dental and optician friends tell me they feel the net income to be 50% of gross income, making £2,275 and £1,600, respectively, while two chemists were unwilling to pass an opinion as they said overheads were covered by other lines. Assuming a doctor's overheads to be 33½%, the average net income is just over £1,050. I read in a daily paper of May 20 that "Mr Bevan's aim is to give the average efficient dentist a net income of not less than £1,788 per annum," so that surely in fairness the average efficient doctor should be worth at least £2,000 per annum net, and this should be tied to the average number of patients per doctor. Incidentally, in many areas the capitation fee was less than 17s last year, and it is surely time we demanded, not asked for, 30s per head at least for the first 2,200 patients and 20s for any others up to a maximum of 3,500.

Association Notices

Diary of Central Meetings

JUNE

- 21 Tues Conference of Anaesthetists Group, 2 p.m.
- 21 Tues World Medical Association—Ladies' Committee, 4.30 p.m.

JULY

- 7 Thurs Joint Committee on Association of the General Practitioner with Hospitals, 2 p.m.
- 7 Thurs Radiologists Group Committee, 2 p.m.

Branch and Division Meetings to be Held

- OXFORD DIVISION—Wednesday, June 22, Visit to the Atomic Energy Research Establishment, Harwell.
- ROCHDALE DIVISION—At Rochdale Infirmary, Sunday, June 19, 6 p.m., annual general meeting. Consideration of Annual Report of Council, election of officers for 1949-50, instruction of Representative to A.R.M. (Meeting adjourned from June 10).
- SURREY BRANCH—At Town Hall, Castlefield Road, Reigate, Wednesday, June 22, 2.30 p.m. Annual meeting. Presidential address by Dr L. J. Barford "Towards a Better Understanding of Rheumatism." Visits to Redhill Aerodrome, Fuller's Earth Union Works, Redhill, and Mullard's Radio Research Works, Redhill.

Meetings of Branches and Divisions

NORTH OF ENGLAND BRANCH

A spring course of scientific meetings was held at the Royal Victoria Infirmary, Newcastle-upon-Tyne, during February and March.

The first meeting held on Feb 24 was well attended and consisted in a demonstration by Dr C. N. Armstrong on Simmonds's disease.

Several cases were shown and the disease was discussed in detail. Mr C. Gordon Frwin then delivered an entertaining and instructive lecture on his recent American tour.

The second meeting, on March 10, consisted in a demonstration by Mr J. D. Rose of excellent lantern slides and cases dealing with various forms of ulceration and gangrene. This was followed by a lecture on "Medical and Veterinary Science" by Mr W. Lyle Stewart, who dealt in some detail with the condition of swayback in sheep and other dietary deficiencies, as well as some infective disorders of common interest to the medical profession and veterinary surgeons.

The last meeting was held on March 31, and over 200 doctors and students were present. The whole evening was devoted to a discussion of obstetrical problems and was arranged by Professor E. Farquhar Murray. Mr Stabler gave an interesting and practical account of what to do until the arrival of the flying squad. Dr William Hunter showed a film in support of his description of the care of the perineum during labour, and Mr Linton Smith discussed threatened abortion and described the experiences in the past few years at the Newcastle General Hospital. Professor E. Farquhar Murray discussed the present position of midwifery. The meeting ended with a description by Mr Harvey Evers of the third stage of labour and its complications, and was made particularly interesting by the many historical references.

CHelsea AND Fulham Division

A meeting of the Chelsea and Fulham Division was held on May 20, with the Kensington and Hammersmith, Westminster and Holborn, and Wandsworth Divisions as guests. The chairman, Dr R. Nelson Ford, introduced Dr Ronald Gibson, Hon. Secretary of Winchester Division.

Dr Gibson said that Winchester felt strongly that now as never before there must be a strong B.M.A. with every part of it closely knit to the other. After looking into the constitution of the B.M.A. it was decided to draw up a memorandum for submission to other Divisions, and when suggestions and revisions were received on the memorandum their own views had been "sunk" to agree with those of the majority.

After the majority views had been received a revised memorandum had been issued, from this a further revised memorandum had been made, and it was decided that the subject was so important that a special representative meeting should be called. The main points for discussion were the Secretariat and Representative Body (the two units which link up the Council with the periphery), and the Constitution of Council.

The present Council, which consisted of one-third of its members directly representing the Divisions and two-thirds not directly representing the Divisions, was not considered democratic. It was thought that the correct proportion was at least two-thirds to be directly represented and one-third not directly represented.

It was felt that the Secretariat were able and very hard-working men but were not sufficiently in contact with the periphery. The Secretariat must go out to the periphery and not wait in Headquarters for people to come up and contact them. Winchester suggested that these Regional Secretaries should be free from as much committee work as possible so as to have time to meet individual members.

Something must be done to strengthen the Representative Body and make more effective the discussion of resolutions which came before it. The Winchester scheme, which had a reasonable amount of support, was that the Divisions should first of all put up their resolutions to Branch Councils, and they should go from the Branch to an Agenda Committee. Winchester suggested that the Divisions should submit their resolutions, and if not satisfied with the action of the Branch Council could retain the power to send them direct to the Representative Body, the object being to strengthen the B.M.A. and bring each unit as near as possible.

Dr L. Potter, Assistant Secretary, B.M.A., said that it had been for many years the policy of the Council to decentralize so far as possible, and a great deal of controversy had gone on as to whether a Secretary should be resident in a Region. He was of the opinion that he would be of far more use if he were in close contact with work at Headquarters. All Secretaries had access to all Committees, but even so it was difficult to keep abreast of the manifold activities. Regional offices were being set up.

Dr Gorsky emphasized that he was in sympathy with the reorganization of the whole organization, but that Dr Gibson's idea of strengthening the B.M.A. was to revolutionize the Representative Body.

Dr C. Watney Roe asked the meeting to bear in mind the instructions given to their representatives on March 18 to press for at least two-thirds direct representation on the Council and the cessation of elections by the R.B. Now that the Council were also Trustees of the British Medical Guild this was doubly important.

The chairman, Dr Ford, suggested that an age limit for membership might be imposed.

Dr Milligan, chairman of Westminster Division, proposed a vote of thanks to Dr Gibson.

WANDSWORTH DIVISION

At the annual meeting of the Wandsworth Division, held on May 31, the following appointments were made for the year 1949-50: chairman, Dr H. Alexander; vice-chairman, Dr D. W. Jackson; hon. treasurer, Dr R. J. Saunders; hon. secretary, Dr T. J. Lee; assistant hon. secretaries, Dr C. J. Grosch and Dr G. R. Boyes; representatives to A.R.M., Dr Alexander, Dr G. R. Boyes, Dr Grosch, and Dr T. J. Lee; representatives on Branch Council, Dr Cornick, Dr Jackson, Dr D. Billig, Dr J. G. H. McNabb, and the hon. secretaries *ex officio*.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY JUNE 25 1949

THE MIND OF MECHANICAL MAN*

BY

GEOFFREY JEFFERSON, C.B.E., F.R.S., M.S., F.R.C.S.

Professor of Neurosurgery, University of Manchester

Brain-Mind Relationship

No better example could be found of man's characteristic desire for knowledge beyond, and far beyond, the limits of the authentic scientific discoveries of his own day than his wish to understand in complete detail the relationship between brain and mind—the one so finite, the other so amorphous and elusive. It is a subject which at present awakes a renewed interest, because we are invaded by the physicists and mathematicians—an invasion by no means unwelcome; bringing as it does new suggestions for analogy and comparison. We feel perhaps that we are being pushed, gently not roughly pushed, to accept the great likeness between the actions of electronic machines and those of the nervous system. At the same time we may misunderstand this invitation, and go beyond it to too ready an affirmation that there is identity. We should be wise to examine the nature of this concept and to see how far the electro-physicists share with us a common road. Medicine is placed by these suggestions in a familiar predicament: I refer to the dangers of our being unintentionally misled by pure science. Medical history furnishes many examples, such as the planetary and chemical theories of disease that were the outcome of the Scientific Renaissance. We are the same people as our ancestors and prone to their mistakes. We should reflect that if we go too far and too fast no one will deride us more unashamedly than the scientists who have tempted us.

Discussion of mind-brain relations is, I know well, premature, but I suspect that it always will be premature, taking heart from a quotation that I shall make from Hughlings Jackson—not one of his best-known passages—because it may have been thought to be a sad lapse on his part. I believe it myself to be both true and useful, and so I repeat it.

"It is a favourite popular delusion that the scientific inquirer is under a sort of moral obligation to abstain from going beyond the generalization of the observed facts, which is absurdly called 'Baconian induction.' But anyone who is practically acquainted with scientific work is aware that those who refuse to go beyond fact rarely get as far as fact; and anyone who has studied the history of science knows that almost every great step therein has been made by the 'anticipation of Nature'—that is, by the invention of hypotheses which, though not verifiable, often had very little foundation to start with."

He concludes by saying that even erroneous theories can do useful service temporarily. He was no doubt thinking of his own early clinical researches on local epilepsy, the

theory of which necessitated crisp localization of motor function, although when first he proposed it the physiological world could not as yet support him. Had he waited for certainty he would never have got near it as early as he did.

So Jackson hinted, and Darwin in comparable words agreed with him. In more recent times K. J. W. Craik rightly drew attention to the real method of scientists, which is to see whether some idea can be substantiated by experiment. They begin without bothering their heads about rigid definitions of what they are doing. Robert Boyle was not interested in making a law but in finding out what happened when gases were compressed. The results happened to be generalizable in a formula. It is the philosophers who insist on logistic definitions which are the more perfect the more they leave out of the vast realms of human striving and usefulness. The so-called Laws of Science had generally no very tidy beginnings. They are no more than science recollected in tranquillity, and not the conscious aim of the eponymous makers of the crucial and revelatory experiments. It may be that the poet who tries to crystallize a moving experience into an immortal line is using his wits in a very similar manner. We must beware of making science too rigid, self-conscious, and pontifical. A. N. Whitehead confessed to me once that he found that he had escaped from the certainty and dogma of the ecclesiastics only in the end to find that the scientists, from whom he had expected an elastic and liberal outlook, were the same people in a different setting. I am encouraged, therefore, to proceed in the hope that, although we shall not arrive at certainty, we may discover some illumination on the way.

Ancient Automata

Before we glance at the new vistas of mechanization opening before us, let us spare a few moments to look at the past, where we shall find that the possibility of building automata has been one of man's dreams since the days of the Trojan horse—a simile more metaphorical than strictly accurate. In the seventeenth century, that era of scientific awakening, there was great interest in possible replicas of animals and men. Florent Schuyt, in 1664, gives several instances, such as the wooden pigeon of Archytas of Tarentum which flew through the air, suspended by counterweights. There was a wooden eagle, that of Regiomontanus, that showed an Emperor the way to Nuremburg, and a flying fly by the same maker. There was an earthen head that spoke; but, above all, a marvellous iron statue that knelt before the Emperor of

*The Lister Oration delivered at the Royal College of Surgeons of England on June 9, 1949.

Morocco and presented him with a request for a pardon for the man who had made him. There were even greater marvels, such as that incomparable statue the Venus of Daedalus, that had quicksilver in its veins and seemed to be alive, and "an infinity of other similar automata, moving and even speaking machines which Coelius Rodiginus mentions in his book on antiquities, and Kircher and many others describe." Gafford, in 1629, had written of statues of men and women which moved and spoke and played musical instruments, birds that flew and sang, lions that leaped, and a thousand other marvels of the inventions of man which astonished the people.

That most of the foregoing examples were no more than fables, or huge exaggerations of a grain of truth, we may be very sure. But there was some foundation for them in the many marvels which the traveller might see with his own eyes at that day, or soon after, such as the water gardens of Tivoli and Pratolino, at Saint Germain-en-Laye, at Fontainebleau, at Augsburg and Salzburg. Water- or wind-power and clockwork were the only sources of energy available, but they caused movement in some pretty toys, and although the figures moved clumsily, yet move they did. As the traveller approached a grotto, for instance, and as he stood admiring, he pressed unwittingly a lever hidden beneath a stone, causing Neptune to come forward with his trident raised to defend a water-nymph, whilst the bathing Diana withdrew among the reeds.

If such wonders had already been constructed for the pleasure of noblemen and the entertainment of their guests, how much more perfectly might not the serious scientist contrive a cunning replica of a living thing. As only too often happens, to conceive it possible was as good as its conversion into fact. It could be, therefore it was. I am sure that that is our own temptation.

Descartes's Postulation

The first convincing postulation of mechanical perfection was of course that of Descartes, who believed that animals, though live things because their hearts were hot (Galen's idea), were entirely reflex in their complicated actions, doing all that they did because their construction compelled them. They had no souls, no minds, and therefore no free will. He expressed himself in a manner which could scarcely be bettered as a fair exposition, up to that moment, of the problem of automata. His views are very apposite to the present day, which has become more Cartesian than it realizes. It should, he thought, be perfectly possible to construct an automaton that would behave not only like an animal but, in so far as he was an animal, like a man, because the organs of man and animal were in the main the same. There was an eventual difference: he saw plainly that it reposed in the highest qualities of man's mind and soul.

Descartes made the point, and a basic one it is, that a parrot repeated only what it had been taught and only a fragment of that; it never used words to express its own thoughts. If, he goes on to say, on the one hand one had a machine that had the shape and appearance of a monkey or other animal without a reasoning soul (i.e., without a human mind) there would be no means of knowing which was the counterfeit. On the other hand, if there was a machine that appeared to be a man, and imitated his actions so far as it would be possible to do so, we should always have two very certain means of recognizing the deceit. First, the machine could not use words as we do to declare our thoughts to others. Secondly, although like some animals they might show more industry than we do, and do some things better than we, yet they would

act without knowledge of what they were about simply by the arrangement of their organs, their mechanisms, each particularly designed for each particular action (cp. Karel Capek's *Robots*). Descartes concluded: "From which comes that it is morally impossible that there be enough diversity in a machine for it to be able to act in all the occurrences of life in the same way that our reason would cause us to act. By these means we can recognize the difference between man and beasts." He could even conceive a machine that might speak and, if touched in one spot, might ask what one wanted—if touched in another that it would cry out that it hurt, and similar things. But he could not conceive of an automaton of sufficient diversity to respond to the sense of all that could be said in its presence. It would fail because it had no mind.

Apart from this difference—a vital one indeed—the body seemed undeniably to be a sum of mechanisms. It was so crystal-clear to Borelli and the new scientists that both animal and human bodies were nothing more than a collection of pumps, reservoirs, bellows, fires, cooling and heating systems, tubes, conduits, kitchens, girders, levers, pulleys and ropes, that there was little left to marvel at. Let the vulgar gape, let the devout feel gratitude to God—it was all very plain to the scientist of that age. It was not plain as they thought. Time has shown that hidden in the materials of which this body is composed are all kinds of biochemical ingenuities. It is a chemical engine such would have astonished the mechanics. Give a man, take the simplest of all examples, a beautifully efficient set of aluminium bones in place of his original skeleton and he will die of some unpleasant blood disease because bones are living organs as well as props.

There certainly are things to marvel at, and no small wonders they are. One is the truly extraordinary efficiency of the living organism as judged by weight, energy output and fuel consumption by comparison with any machine whatever; another is its ability to carry on with its own feed-back controls for decades, without adjustment or repair. In the long run, of course, scientific method made great use of the mechanical likenesses that so impressed the savants of the scientific Renaissance. A great service had been done by destroying mystery and by discrediting Platonic and Aristotelian essences and humours. Most of our advances have been made by use of technical methods common both to machines and to living things. But all our advances have depended on observation of the thing itself, accepting likeness to mechanism only as analogy and not as identity.

I fancy that no one will disagree in summary of the foregoing that, however like the various processes are to other things in physical nature, however amenable they are to examination as physico-chemical processes, they remain unmistakably themselves. We shall reach the same conclusion about the brain—that, however its functions may be mimicked by machines, it remains itself and is unique in Nature. Descartes solved the difficulty by making mind supernatural, placing an immaterial mind independent of organism in the pineal. This was the age-old refuge of those faced with the inexplicable in Nature, as we still see in primitive peoples and in the superstitious. We may well doubt to-day whether a supernatural agency is the basis of mental process. But it was doubted in Lister's time. In 1870 T. H. Huxley reluctantly concluded: "I can find no intelligible ground for refusing to say that the properties of protoplasm result from the nature and disposition of its molecules . . . and if so, it must be true, in the same sense and to the same extent, that the thoughts to which I am now giving utterance, and your thoughts regarding them,

are the expression of molecular changes in the matter of life which is the source of our other vital phenomena."

The passage of time which has led us to accept so much has done little to make this conclusion either less true or much more acceptable than it was to Huxley himself. To admit it seems to confess to a certain ordinariness about mind, an ordinariness to which the richness and plasticity of its powers seem to give the lie and in revenge to demand a stupendous physical explanation. And there is something more. Since no thinking man can be unaware of his fellows and of the political scene he will find that the concept of thinking like machines lends itself to certain political dogmas inimical to man's happiness. Furthermore, it erodes religious beliefs that have been mainstays of social conduct and have brought happiness and serenity of mind to many. These possibilities would have leaped to the forefront of Joseph Lister's mind as they do to mine. But I hope to show that we can take courage.

Modern Automata

Ingenuity of invention at the present time confronts our more sophisticated eyes with models as seductive as were the cruder automata of old. By means of electric motors, thermo-couples, photo-electric cells, radio tubes, sound receptors, and electrical resistances variable to moisture it should be possible to construct a simple animal such as a tortoise (as Grey Walter ingeniously proposed) that would show by its movements that it disliked bright lights, cold, and damp, and be apparently frightened by loud noises, moving towards or away from such stimuli as its receptors were capable of responding to. In a favourable situation the behaviour of such a toy could appear to be very lifelike—so much so that a good demonstrator might cause the credulous to exclaim "This is indeed a tortoise." I imagine, however, that another tortoise would quickly find it a puzzling companion and a disappointing mate.

It is the infinite variety of the behaviour of the world of animals that confuses us. The stage is too vast, the cast too numerous, the qualities of their performances too varied. We should not show any hesitation in attributing conscious mental processes to animals to-day. Greatly though information has increased, the field study of animals in their natural state is with difficulty pursued over long periods, so that we have but short chapters from their lives, and some are too shy, too evasive, or too episodic in their sojourns to allow of continuous recording. We should find great difficulty in grading animal minds. Such knowledge as we have is enough to teach us that even among creatures of the same genera there are great differences in the cleverness of individuals. There are not only clever dogs and dull ones, but clever hens and stupid hens, attractive hens (to the cock) and plain ones, and, for all we know, clever and lovely flies, clever elephants, clever snakes and fish, with dull-witted brothers and ugly sisters. Obstinacy, no doubt, varies in the mule.

At what level in the animal scale something that can be called mind appears for the first time we do not know. J. Z. Young's experiments show that even an octopus can learn, be so puzzled by problems set it as to be made what we might be allowed to call neurotic. That this could happen to monkeys we already knew from ingenious experiment, and now the reproduction of bewilderment that paralyses action in such low forms of life is singularly interesting. The child, confused by its teachers and unable to grasp the logic of its lessons, is but a more complex example of the puzzled octopus. It seems to me likely that the number of synapses in a nervous system is the key to the possible variations in its behaviour. Provided that the

neurones are not too numerous and consequently the synaptic patterns of alternative routes for impulses not too varied, it is not difficult to imagine that some, though not all except the simplest, animal behaviour is the result of a pattern of reflexes, much more complicated, it is true, than the plain push-button-and-answer of some spinal reflexes.

But neither animals nor men can be explained by studying nervous mechanics in isolation, so complicated are they by endocrines, so coloured is thought by emotion. Sex hormones introduce peculiarities of behaviour often as inexplicable as they are impressive (as in migratory fish). We should not have any real idea how to make a model electronic salmon however simple relatively its nervous system is, whilst birds would be as far beyond us again. I can see that, although a good deal of instruction might be got from varying the proportion of, say, photo-electric cells, thermo-couples, and sound-receivers perhaps above and below the range of human hearing to see how variations affected the antics of a model, it remains uncertain how far we should be truly enlightened on the obscurities of animal behaviour. Olfaction, which plays so large a part in some creatures, would be particularly difficult to mimic. So would the effects of satisfaction of appetites of all kinds and of fatigue—such important influences.

When all is said—and much more could be said on both sides—we emerge with the conviction that, although much can be properly explained by conditioned reflexes and determinism (in which idea mechanism lurks in the background), there is a fringe left over in which free will may act (i.e., choice not rigidly bound to individual precedent), a fringe that becomes larger and larger the more complex the nervous system. Both views are correct in their own spheres; neither is wholly correct for everything. I accept here the emendation of Niels Bohr, who sees this as the counterpart of the impossibility of fully describing the electron either as a point or as a wave. It is either, according to how it is examined or in what circumstances. This paradox the mathematicians call the Law of Complementarity, and are not afraid to regard the same thing as true in two different guises. We may do well to follow their example.

The Nervous Impulse

The electronic computing machine works as a logical system, making a choice between "yes" and "no" at a great number of points in a vast chain, with the speed of electricity. Because it uses wireless valves, wired circuits, mercury tubes, condensers, and all the paraphernalia of electricity it works thousands of times faster than can the human brain. Before we proceed further in considering machines we must see how far we can go in saying that our own nervous system is electrical. We shall see that it is not so, in the layman's meaning of the term, but the electrical processes that accompany its actions afford problems of absorbing interest. The fastest known nerve impulses in mammalian nerve or spinal cord travel at about 140 metres per second, the slowest anything down to 0.3 metre per second. What their speed may be in the brain we do not know, but very likely perhaps it does not differ much from these figures. The passage of impulses through single synapses is known by the work of Lorente de Nó and others to cause a delay of 0.75 millisecond. Such delays, and there are sure to be many in the cortex, impose a certain additional slowness on nervous actions.

The flashing speed of thought which so much impresses us is, it seems, a rather slow affair, but in view of the short distances that impulses have to travel in the brain the rate is fast enough to appear instantaneous to us. It is true

that, although the electrical current cannot itself be slowed down from its normal 1,000 ft. per microsecond, it is possible to slow down the arrival of an impulse by devices such as delay systems, and especially by the trigger systems, in which each component excites the next, at a rate that can be made inferior to conduction in nerve. There is, it seems, no limit to the slowing which could be imposed, down even to 1 foot an hour. This would entail complex apparatus. For many years nothing recognizably the counterpart of such systems could be found in the structure of the nerve fibre, but there are those who believe now that the retardation is at the nodes of Ranvier, with high-speed leaps between each node (the "saltatory theory" of conduction). Significantly, nodes of Ranvier have been found in the tracts of the spinal cord.

It remains an anomaly that the speed of the nervous impulse is usually slower in the bare fibres of non-medullated than in medullated nerve, as if the nerve sheath increased the speed. To the surgeon the results of nerve injuries and the long delay in recovery seemed to negative completely the electrical nature of the impulse. It certainly would be impossible if we thought of electrical currents flowing along plain copper wires. But the delay in recovery is accounted for equally well in either view on the ground that the passage of the impulse requires a perfect conductory system, which, unlike copper wire, takes time to repair. Physiological conduction demands more than anatomical continuity, the axons must be a certain size and the sheath a certain thickness, as Young shows, and it is conceivable that the sheath needs to acquire certain physical properties proper for polarization. Whichever way one looks at it the speed of the nervous impulse presents us with a problem in electricity as a biological fact that is so special as to be unique.

Lastly, although electronic methods permit of much more local, more individual questioning of elements in the nervous system, we must not overlook the chemical agencies which transmission demands and from which nerve cells derive their energy. It seems very plain that if the nervous system is examined by electrical methods answers must be obtained in terms of electricity. But if it is examined in terms of chemistry, as Sir Henry Dale and G. L. Brown have done, the same thing now appears as a wonderfully implemented electro-chemical machine. There may be other methods of investigation still to be discovered.

It would probably be wrong to say that electrical methods are more delicate than chemical, yet it is certainly much easier to render an account of nervous actions and to represent the results of understandable diagrams by the former than by the latter means. A one-sided view is only too easily acquired, but let the artificers remember chemistry, for metabolic disorders can block transmission—the "invisible lesions" of clinical neurology of which Sir Charles Symonds has written. The recollection that chemical agencies and enzyme actions are no doubt eventually explicable in physical terms does not entirely remove the force of this reminder.

Calculating Machines

These lines of thought, however elementary, seemed to me a necessary prologue before we come to consider systems which have a purely electronic structure. We shall be right in concluding that it does not greatly matter what the nervous impulse really is, except that, vastly multiplied, it is part of a communication system, a self-controlled information system (self-controlled because of its integrating feed-backs), and could therefore be compared with man-

made systems in these classes. Such systems happen to be a peculiarly rich development of our own times. But we shall be quite wrong if we approach the subject on any other terms except those of analogy.

To be just, nothing more than analogy is claimed by most of their constructors (some, like Professor Williams, do not go so far even as that), but there is a grave danger that those not so well informed will go to great lengths of fantasy. If we see that some nervous tissues behave like some electronic circuits we must all the time remember that the resemblance is with fragments of the nervous system and not with the whole integrated nervous system of man. It is only right when we do so that we recollect something else, that we cannot be sure that the highest intellectual processes are still carried out in the same way. Something quite different, as yet undiscovered, may happen in those final processes of brain activity that results in what we call, for convenience, mind.

The histological pattern of the human cortex leaves us with a host of questions unanswered. We may be in the familiar position that I sketched in earlier passages of stretching our knowledge to cover something to which it does not apply. Abstract thinking may not be a matter of neurone mechanics as we know them at lower levels. But let us proceed for the moment by supposing that the system remains the same throughout—and a large assumption it is—and that it is for the moment comparable with something of a different material composition but with a similar plan. The mechanisms of calculating machines are outside the province of neurologist or surgeon, and I have to rely upon and gratefully acknowledge the assistance of Professor F. C. Williams, professor of electro-technics in my own university, and the information gleaned from Dr. Wiener, of Boston, in his entertaining book on the new science that he has christened "Cybernetics" (1948).

Computing machines use very many fewer "neurones" than has the brain. One may compare the 10,000,000,000 cells of Adrian's estimate with the 20,000 valves of the first big American machine ENIAC at Princeton, and the 1,000 of Professor Williams's newer and more efficient experimental and most ingenious instrument in Manchester McCulloch, of Chicago, was reported as saying that a model that contained valves and wiring anything approaching in number the neurones in the human nervous system would require a building the size of the Empire State Building to house it and the complete electrical output of Niagara Falls to run it. Calculating machines certainly consume great quantities of electricity and generate considerable heat. It is probable that McCulloch's estimate is lavish because the brain almost certainly sends out and receives the same message through several fibres and cells so that we have more nervous tissue than we need and more certainly, than we use if the meagre effects of excisions from some areas mean what we think they mean.

Wherein do any analogies lie? They lie in certain likenesses between wireless valves and nerve cells in this way, that the valves can be so wired as to store messages, to show the Sherringtonian principles of "convergence" and "divergence," can be inhibited from action, and may be arranged so as only to transmit a message (a symbol in terms of electricity) if they are receiving impulses from one or several other valves and not to transmit if other excitations fail to come in. The likeness between such an arrangement and that of the impulses arriving in a nerve cell through its dendrites and the behaviour of neurone pools is so close as to convince us that in these actions some nervous tissues with simple patterns behave extremely like

some electronic circuits.* It gives additional support to the belief that human tissues behave according to some physical laws discoverable elsewhere in Nature, without surrendering their own individuality. This is a belief old enough to be both useful and respectable.

The fact that calculating machines can be made to store electrical charges representing numbers for long periods of time suggests that there is "memory" in the machine, which must in fact "remember" how far it has got with a calculation in order to be able to proceed, just as we do ourselves. It must also "remember" all the data and the procedure leading to solution. It retains its "memory" until it is cleared of its charges. Using electronic instead of nervous impulses it can carry out calculations with such great rapidity that it will solve a simple calculation in milliseconds, and in an hour one that would employ a mathematician several months. We are invited to consider that the memory that the machine has in the form of stored charges is perhaps the same as memory in man or in animal, as a "charge" in a cell or a group of those millions of cells whose individual uses we do not know.

All that one is entitled to say is that it could be something of that kind, but that the electrical machine offers no proof that it is so. We might guess so much without a machine, nor does it tell us what the nature of the "charge" in a nerve cell is, except to assume that it is electrical (for which there is no present justification). Damage to large parts of the human brain, entailing vast cell losses, can occur without serious loss of memory, and that is not true of calculating machines so far, though so large a one might be imagined that parts of it might be rendered inoperative without total loss of function. It can be urged, and it is cogent argument against the machine, that it can answer only problems given to it, and, furthermore, that the method it employs is one prearranged by its operator. The "facilities" are provided and can be arranged in any order by "programming" without rebuilding.

It may be objected that the second argument is equally true of man; our difficulty is in his case that we have not seen the blue-print from which he was constructed, and that we have been baffled by our attempts to reconstruct it. The first objection can be met by the counter proposition that man himself answers only such propositions as are put to him by his environment, and takes us back indeed to Aristotle's "Nihil est in mente quod non," etc., that our minds are built by education and experience data, processed by the machine, our brain. But the calculating machine which man makes himself throws no light on this problem; it only appears to do so.

There is another analogy of which Wiener has made interesting use. It is this: that computing machines with complicated circuits may develop spontaneous functional faults in which the operation circles endlessly in a closed loop instead of proceeding in the way intended. This is a not uncommon "disease" of electronic computing machines. It can be cured by cutting off the current, by shaking the machine, or by putting into it a "shock" charge. Wiener makes much of the likeness between this functional machine-illness and the methods employed in curing obsessional diseases in man (sleep or narcosis, leucotomy or E.C.T.). The likeness stands or falls on the acceptance of Moniz's suggestion, and it is no more, than an obsession is a chain reaction in neurone mechanisms by which a dominant idea blocks the normal functioning of mind and behaviour. It is a good analogy, but it neither proves nor disproves the theory that obsessions are in fact exactly of

that kind. They are certainly vastly more complicated than the abnormal "circulation disease" in a calculating machine. I repeat that it is again only analogy, but it is one which the impulsive may much too easily accept as ambivalent proof of identity, simple and diagrammatic.

Wiener made the suggestion that the searching process in automatic telephone exchanges, by which unoccupied circuits are looked for by the electrical equivalents of incoming number combinations, is very likely the counterpart of what happens in the nervous system. This may be true, but the alternative pathways in the cord and brain are so great that "engaged" signals will be rare. "Previous engagement" might, however, account for the failure of some messages to reach consciousness, or explain in different language our inability to do several things at the same time. Comparisons with the scanning processes of television may yet prove instructive. Ideas such as these remind us that we do not need to accept exact similarity for us to look with renewed interest at old problems. They remind us how far we have advanced since we could be satisfied by comparing the nervous system with a hand-operated telephone exchange.

Thinking

The activity of the nerve cells in the grey matter even of an isolated segment of the spinal cord can be demonstrated by electronic detectors. The activity is greater when the cord is in continuity with the brain and falls to a minimum when the roots are divided. Of the vast stream of sense data that pour into our nervous systems we are aware of few and we name still fewer. For it is the fact that even percepts are wordless. Only by necessity do we put a vocabulary to what we touch, see, taste, and smell, and to such sounds as we hear that are not themselves words. We look at a landscape, at the rich carving and majestic architecture of a cathedral, listen to the development of harmonies in a symphony, or admire special skill in games and find ourselves woefully lacking in ability to describe our percepts. Words, as we very rightly say, fail us either to describe the plain facts of these experiences or to impart to others our feelings. Gesture at times speaks more tellingly than tongues.

From these plain truths has arisen the profession of the critic, who has himself to learn and to teach the public to accept a conventional paraphrase, sometimes taking refuge in describing painting in terms of music and vice versa. The variety of the visual and general perceptual scene alone is too great for those frail instruments—words—and it is because of this that literature flourishes. But without using words, though richer in the variety of our experience and with words only just below the surface, our minds are not very dissimilar from those of animals, and it is not difficult to conjecture that a Trappist existence might, for a brief period, be not unpleasant. The development of this theme would take me too far, but it is necessary for us to bear it in mind in considering mechanism and thinking. Granted that much that goes on in our heads is wordless (for if it is not, then we must concede words, an internal vocabulary, to animals), we certainly require words for conceptual thinking as well as for expression. It is here that there is the sudden and mysterious leap from the highest animal to man, and it is in the speech areas of the dominant hemisphere rather than in the pineal that Descartes should have put the soul, the highest intellectual faculties.

It is almost boring to repeat that it is because he has a vocabulary that man's intellectual progress has been made possible—by the day-by-day record of how far he has gone in his pilgrimage towards finite knowledge. that journey

*I am obliged to my colleague, Professor Schlapp, for deductions which he drew chiefly from the Cambridge machine and for other wise comments.

without an end. We remember more, that language is not static, but that neologisms continually mark our progress not only in general ideas but in science. We use to-day scores of scientific terms that men who lived as recently as Priestley, Lavoisier, and Darwin would not understand. It is not enough, therefore, to build a machine that could use words (if that were possible), it would have to be able to create concepts and to *find for itself* suitable words in which to express additions to knowledge that it brought about. Otherwise it would be no more than a cleverer parrot, an improvement on the typewriting monkeys which would accidentally in the course of centuries write *Hamlet*. A machine might solve problems in logic, since logic and mathematics are much the same thing. In fact some measures to that end are on foot in my university's department of philosophy. If the machine typewrites its answers, the cry may rise that it has learned to write, when in fact it would be doing no more than telegraphic systems do already.

Nor must we overlook the limitations of the machines. They need very intelligent staffs to feed them with the right problems, and they will attempt the insoluble and continue at it until the current is switched off. Their great advantage is their speed compared with a human mind, and I have given reasons for that. But, it may be asked, is that so very much more marvellous than the crane that can lift so much more than can a man or than an automobile that can move so much quicker?

The great difference in favour of the calculating machine as compared with the crane, and I willingly allow it, is that the means employed are basically so similar to some single nervous lay-outs. As I have said, the schism arises over the use of words and lies above all in the machines' lack of opinions, of creative thinking in verbal concepts. I shall be surprised, indeed, if that gap is bridged, for even supposing that electrical charges could be made to represent words, what then? I cannot see that anything but jargon would result. Not until a machine can write a sonnet or compose a concerto because of thoughts and emotions felt, and not by the chance fall of symbols, could we agree that machine equals brain—that is, not only write it but know that it had written it. No mechanism could feel (and not merely artificially signal, an easy contrivance) pleasure at its successes, grief when its valves fuse, be warmed by flattery, be made miserable by its mistakes, be charmed by sex, be angry or depressed when it cannot get what it wants.

Conclusion

I conclude, therefore, that although electronic apparatus can probably parallel some of the simpler activities of nerve and spinal cord, for we can already see the parallelism between mechanical feed-backs and Sherringtonian integration, and may yet assist us in understanding better the transmission of the special senses, it still does not take us over the blank wall that confronts us when we come to explore thinking, the ultimate in mind. Nor do I believe that it will do so. I am quite sure that the extreme variety, flexibility, and complexity of nervous mechanisms are greatly underestimated by the physicists, who naturally omit everything unfavourable to a point of view. What I fear is that a great many airy theories will arise in the attempt to persuade us against our better judgment. We have had a hard task to dissuade man from reading qualities of human mind into animals. I see a new and greater danger threatening—that of anthropomorphizing the machine. When we hear it said that wireless valves think, we may despair of language. As well say that the cells in the spinal cord below a transverse lesion "think," a heresy that Marshall Hall destroyed 100 years ago. I venture

to predict that the day will never dawn when the gracious premises of the Royal Society have to be turned into garages to house the new Fellows.

I end by ranging myself with the humanist Shakespeare rather than the mechanists, recalling Hamlet's lines: "What a piece of work is a man! How noble in reason! how infinite in faculty; in form, in moving, how express and admirable! in action, how like an angel! in apprehension, how like a god! the beauty of the world! the paragon of animals!" In that conclusion, if not always in my approach to it, I feel confident that I should have won the approval of that bold experimenter and noble character in whose remembrance this oration was founded.

THE USE IN CHILDREN OF PROCAINE PENICILLIN WITH ALUMINIUM MONOSTEARATE

BY

JOHN L. EMERY, M.D., D.C.H.

Clinical Pathologist; Lecturer in Pathology, University of Sheffield

L. M. ROSE, B.M., M.R.C.P.

Resident Clinical Assistant, Hospital Unit

SHEILA M. STEWART, B.Sc.

Bacteriologist; Demonstrator in Bacteriology, University of Sheffield

AND

E. J. WAYNE, M.D., F.R.C.P.

*Professor in Pharmacology, University of Sheffield;
Physician, Children's Hospital*

(From the Children's Hospital, Sheffield)

Frequent intramuscular injections of penicillin preparations to children often cause much pain and unhappiness. There have been many attempts to prolong the therapeutic action of a single injection by using penicillin added to bases relatively insoluble in water. Such preparations are based on the premise that a single injection will introduce into the body a depot of penicillin which will be released slowly, thus achieving a therapeutic concentration in the blood over a prolonged period.

Procaine penicillin G, described by Salivar, Hedger, and Brown (1948) and Sullivan, Symmes, Miller, and Rhodhamel (1948), is a relatively insoluble equimolecular combination of procaine together with the sodium or potassium salts of penicillin G. It is usually prepared as a suspension in a base of refined sesame or arachis oil. The clinical value of procaine penicillin has been described by Herrell, Nichols, and Heilman (1947) and Boger, Orritt, Israel, and Flippin (1948). In adults it is claimed that adequate blood levels can be demonstrated up to 24 hours after one injection of 300,000 units. Similar levels were found after single daily injections in children by Carson, Gerstung, and Mazur (1949). That blood levels in children 24 hours after a single injection may be variable has been shown by Emery, Stewart, and Stone (1949). It is realized, however, that procaine penicillin has considerable advantages over previous preparations.

Buckwater and Dickenson (1947) described a new vehicle for the intramuscular administration of penicillin, in which penicillin salts are suspended in peanut oil combined with aluminium stearate. It would seem that the aluminium ester

produces a unimolecular envelope to the penicillin particles, to some extent preventing solution of the penicillin. (This preparation is not to be confused with the aluminium salt of penicillin, the experimental activity of which was reported by Reid (1947).)

Thomas, Lyons, Romansky, Rein, and Kitchen (1948) studied the effect of a single injection of various penicillin salts in a peanut-oil medium together with 2% (w/v) of aluminium monostearate. They found that the absorption of penicillin from the peanut-oil preparation containing aluminium stearate was delayed as compared with the absorption from the same salts in peanut oil alone or in peanut oil with wax. A single intramuscular injection of procaine penicillin in peanut oil with aluminium monostearate resulted in blood concentrations being maintained over a longer period than after a single injection of similar preparations of sodium or aluminium penicillin. It was further observed that the smaller the size of the individual particles of the preparation the greater the prolongation. The greatest prolongation was when 95% of the particles were under 5μ in diameter.

Similar observations on the importance of particulate size have been made with respect to suspensions of procaine penicillin by Dowling *et al.* (1947) and Welch, Hirsh, Taggart, and Smith (1947). Clinical trials of procaine penicillin in an oil and aluminium monostearate gel have confirmed the production of prolonged blood levels. Robinson, Hirsh, Milloff, and Dowling (1948) found that the majority of their patients had assayable blood levels after 24 hours, while one-third had assayable levels after 48 hours.

This paper records an investigation of penicillin levels in the blood of children following the injection of a preparation of procaine penicillin in arachis oil with 2% (w/v) aluminium stearate.

Method

Dosage was graded according to age. Children over the age of 5 were given the usual adult dose of 300,000 units, which is 1 ml. of the emulsion. Children from 1 to 4 years old were given 150,000 units (0.5 ml.). Under the age of 1 year, some were given 75,000 units and others 150,000 units. Injections were made into the vastus lateralis.

Penicillin serum levels were estimated by the capillary-tube method described by Fleming (1943), using whole blood inoculated with Richard's strain of *Streptococcus pyogenes*. The serum used for assay was from capillary blood collected in Wright's capsules. Control specimens were taken before the injection of penicillin. Daily specimens of blood were taken from all patients for 48 hours; in some it was not possible to continue taking specimens beyond this time. In seven out-patients injections were repeated at the end of 48 hours, and in 11 ambulatory children injections were given daily for three days. In 11 in-patients the serum levels were obtained at one, three, and six hours after the first injection to assay the rapidity of absorption.

The particulate size of the procaine penicillin in the suspension of each bottle used was estimated by direct measurement under the microscope. Over 95% of the particles of the preparation were below 5μ in diameter, which agreed with the claim made by the makers (Imperial Chemical (Pharmaceuticals), Ltd., Manchester).

Note on Technique of Injection.—The chief disadvantage of this preparation is the difficulty of drawing the suspension into the syringe. A wide serum needle can be used. A more economical method is to pump air into the bottle, using a No. 1 Record needle, thus causing the pressure in the bottle to fill the syringe. If the injection is made at

right-angles to the skin and muscle there is a tendency for the material to leak back along the needle track, particularly if the muscle is held tense. This back leak is almost entirely eliminated by making an oblique injection.

Results

The serum penicillin levels obtained in 11 patients one, three, six, and 24 hours after the injection of procaine penicillin with 2% aluminium stearate are given in Table I.

TABLE I—Serum Penicillin Levels in 11 Children in Bed During the 24 Hours Following the Injection of Procaine Penicillin in 2% Aluminium Stearate

Serum Penicillin Level (u./ml.)	Hours after Injection			
	1	3	6	24
8		1		
4		2		
2	3	3	1	1
0.75	1	2	2	
0.50	4	3	3	3
0.25				5
0.12				2

Dose of penicillin: 0-1 year, 75,000 units, 1-4 years, 150,000 units; 5-12 years, 300,000 units. The figures give the number of patients showing the tabulated levels at the time intervals.

In all patients the serum level was 0.5 u./ml. or higher at one hour and three hours. At six hours the concentration fell a little, but the minimum level was 0.25 u./ml., and at 24 hours the minimum level was 0.12 u./ml.

An analysis of the daily serum penicillin levels in 66 children of varying ages, following the injection of the aluminium procaine penicillin, is given in Table II. All

TABLE II—Analysis of the Serum Penicillin Levels in 66 Children after the Injection of Procaine Penicillin with 2% Aluminium Stearate

Age Group in Years	Dose of Penicillin (Units)	In- or Out-Patients	No. of Patients	No. of Cases Giving Serum Penicillin Levels of 0.06 u./ml. or Over			
				24 Hours	48 Hours	72 Hours	96 Hours
0-1	75,000 150,000	Mixed	8 6	8 6	8 3 of 3	4 of 5 2 of 2	2 of 2
1-4	150,000 150,000 300,000	1 P O P 1 P	14 11 1	14 10 1	11 of 11 9 of 10 1	7 of 10 — 1	7 of 7 — 1

0-13	As above	O P 1 P	8 3	Reinjection after 48 hours	8 3 of 3	5 of 5 3 of 3	—

the children under 1 year old gave a serum level of 0.06 u./ml. or over at the end of 48 hours after the injection. Four of five receiving the smaller dose of 75,000 units had a level of 0.06 u./ml. or over at 72 hours.

All the 14 in-patients aged 1-4 who were given 150,000 units had a level at least 0.12 u./ml. at 24 hours and 0.06 u./ml. at 48 hours, and seven of these followed to the end of a fourth day showed levels of 0.06 u./ml. Of 11 out-patients aged 1-4 given 150,000 units, all except one had levels of 0.06 u./ml. or over at 24 and 48 hours after injection. One child aged 4 was given 300,000 units, and he still had a level of 0.06 u./ml. at the end of four days, when he was discharged.

All the 26 patients aged 5 to 13 given 300,000 units had levels of at least 0.06 u./ml. at 24 hours, as did all 20 examined at 48 hours; 12 of 15 examined at the end of three days showed similar levels. Five of 12 patients of this group showed a level of 0.06 u./ml. after four days.

Eight patients given injections on alternate days maintained levels of at least 0.06 u./ml.

The blood penicillin levels of 11 children who received a daily injection of procaine penicillin with aluminium stearate are given in Table III. In the great majority the levels were above 0.12 u./ml. throughout.

TABLE III.—Serum Penicillin Levels in 11 Ambulant Children given Once-daily Injections of Procaine Penicillin with 2% Aluminium Stearate

Serum Penicillin Levels (u./ml.)	Control	No. of Patients Showing Tabulated Levels at the End of		
		1 Day	2 Days	3 Days
4		1		
2			1	
1		1		2
0.75			1	1
0.5			2	4
0.25			3	3
0.12		5	3	
0.06		2	1	1
0.03		2		
Nil	11			

Dose of penicillin: 0-4 years, 150,000 units; 5-12 years, 300,000 units.

No child showed a general reaction to the injection. One parent stated that her child had walked with a limp for 12 hours afterwards, but on examination we could find no localized swelling or tenderness.

Discussion

This investigation was concerned primarily with serum penicillin levels obtained after the injection of procaine penicillin with aluminium stearate, and no attempt has been made to assess accurately the therapeutic value of the preparation; the clinical results, however, were satisfactory.

The high serum penicillin levels obtained during the first three hours after injection suggest that there is more rapid absorption at this period than later. This is possibly due to absorption before the formation of an inflammatory barrier and to the immediate absorption of any free penicillin already present in the preparation.

The results we have obtained with the preparation are considerably better than those obtained with procaine penicillin without aluminium stearate, and agree very well with the findings of Thomas *et al.* (1948) and Robinson *et al.* (1948) in adults. In the doses we have used a level of at least 0.06 u./ml. was obtained after 48 hours in all but one out-patient. Furthermore, a level of at least 0.06 u./ml. was found in 20 of 22 patients whose blood was examined at the end of three days.

From the results we have obtained it would seem theoretically reasonable to give injections on alternate days, and in the eight children in which this was carried out a level of 0.06 u./ml. or over was maintained. Eleven children were, however, given daily injections to ascertain if there was a summation effect and if it was possible to maintain high levels of penicillin in the blood by this means. Daily injections were carried out for three days, as it was thought that from the persistence of levels in ambulant children for three days only a maximum level would be reached by the end of three days and no higher levels could be reasonably expected later. The results shown in Table III indicate that daily injections not only provide a satisfactory level but give a summation effect. It is clear that the blood penicillin levels are maintained in the great majority of cases above 0.1 u./ml., a level which is bacteriostatic for almost all pathogens other than those showing particular resistance, such as particular strains of staphylococci.

A disadvantage of the preparation is its oily nature, which makes it rather more difficult to administer than aqueous preparations of penicillin. There is also the possibility of sensitization, and possibly a skin test with the preparation

may have to precede treatment. We have not seen any reaction, but we have not given the preparation to any child continuously over a very long period. The possibility of the effects of absorbed procaine after conversion to para-aminobenzoic acid interfering with the action of sulphonamides is largely theoretical and extremely difficult to prove, Carson, Gerstung, and Mazur (1949) could obtain no conclusive evidence on this point when using the earlier simple procaine penicillin, in which the rate of absorption is much greater than in this suspension with aluminium stearate.

This preparation of penicillin seems to have advantages over all previous preparations that have been marketed. It gives an almost painless injection site, minimal local and no general reaction, and in our experience an almost stable concentration of penicillin in the blood for at least 48 hours; and one is confronted with the unusual prospect of deciding at what daily intervals injections should be given.

Summary

Blood penicillin levels have been followed in 66 children of varying ages given graded doses of procaine penicillin in arachis oil with 2% aluminium stearate in which over 95% of the particles were below 5 μ in diameter.

The doses given were 75,000 units (0.25 ml.) and 150,000 units (0.5 ml.) to children under 1 year, 150,000 units to children aged 1-4 years, and 300,000 units (1 ml.) to older children.

There is a rapid initial absorption of penicillin, giving a level above 0.2 u./ml. by the end of the first hour, and this level is maintained for at least three hours.

In all but one case a blood penicillin level of 0.06 u./ml. or more was maintained for at least 48 hours after injection.

Children given daily and alternate daily injections maintain a continual penicillin level in the blood, the daily injection producing higher levels than the alternate daily injection.

We conclude that procaine penicillin in arachis oil with 2% aluminium stearate is a suitable preparation for the daily injection of penicillin.

We would like to thank Dr. T. Colver, whose patients were used in these estimations, our nursing and medical colleagues for their co-operation, and Miss Dorothy Lee for laboratory technical assistance. The penicillin preparation was kindly supplied by Imperial Chemical (Pharmaceuticals), Ltd., Manchester.

According to a report (B.U.P.) the war in China has led to a great increase in the price of menthol. The stock of this substance in Hong Kong is said to be practically exhausted, and it is almost impossible to obtain more from the interior of China under present conditions. During the war, when Far Eastern supplies were cut off, Brazil developed the production of menthol, which is derived from peppermint oil, but this year's output is estimated to be less than 100 tons, and the United States alone uses between 250 and 300 tons a year.

INJURIES TO THE SUPERIOR LONGITUDINAL SINUS

BY

G. B. BARKER, M.B., B.Ch., D.P.M.

Late Assistant, E.M.S. Neurosurgical Unit

During the six months following D Day, 1944, a considerable number of cases of head injury were received at an E.M.S. neurosurgical unit. These presented every type of injury, with varied signs and symptoms, but among them were a number of injuries which had involved the superior longitudinal sinus (S.L.S.) to a varying degree. These were an interesting group, and 11 of the 26 cases seen were selected for study as presenting fairly clear-cut examples of the S.L.S. syndrome without the complicating factors of other injuries. As a group these cases did very well, and this study is directed with special reference to their follow-up over the last four years.

Anatomy

The S.L.S. begins in the anterior fossa of the skull, at the crista galli, where it communicates with the veins of the nasal cavity or with the angular veins. It runs longitudinally backwards over the convex surface of the cerebrum, as far back as the level of the internal occipital protuberance, and then curves laterally, usually to the right, to form the transverse sinus. Its anatomy has been investigated by Sargent (1910-11), who describes several features of importance. It receives the superior cerebral veins from the mesial surface and from the upper half of each cerebral cortex. The veins from the lower half drain into the Sylvian system and there is an inconstant but adequate anastomosis between the two systems, so that the occlusion of one set of veins is not necessarily accompanied by blockage of the venous outflow from the area which it drains. The upper set of cortical veins group together to form four main channels—the frontal, pre-central, post-central, and occipital veins.

The S.L.S. is accompanied on each side by three main venous channels or lacunae—the frontal receiving the frontal cortical veins, the parietal receiving the pre- and post-central veins, and the occipital receiving the occipital cortical veins. These lacunae vary in size, but Sargent reports one case in which the parietal lacuna on each side measured 15 cm. in length and 2.5 cm. in breadth at its widest part.

The cortical veins terminate in two main ways. Either they run beneath the lateral lacunae and empty into them by means of openings in their floor, the blood then draining through a number of openings into the S.L.S., or they run completely beneath the floor of the lacunae and open direct into the S.L.S.

Injury

Gordon Holmes and Sargent (1915) reported over 70 cases of injury to the S.L.S. from wounds without infection, and discussed the possible pathology of the symptoms in the light of this anatomical knowledge. The present paper deals with a far smaller group, but one which has been followed up for a considerable period. The data have been accumulated from our own notes and from the field medical cards that accompanied the cases. Work was carried out under pressure and the notes are therefore not always as full as one might wish.

Of the 11 patients five were wounded while under shell or mortar fire, two suffered from bomb blast, one from a bullet wound, and one from some bridging equipment

falling on his head. In two cases the history was unobtainable. Four patients retained consciousness and were able to give good and coherent histories. Loss of consciousness in the others varied from ten minutes to four days, but with the exception of this last case and one other the period of unconsciousness was brief, and retrograde and post-traumatic amnesia was very short.

The injury was described as a "lacerated wound" in six of the 11 cases, and these included three cases in which consciousness was retained. Two cases had protruding brain substance and two had penetrating wounds.

Subsequent x-ray examination revealed the presence of a bony depression in the region of the S.L.S. in seven cases; three others had severe bony injury with in-driven bone fragments, and in only one case was there no evidence of bony injury.

Gordon Holmes and Sargent described three main types of wound which correspond to those from which our own cases suffered: (1) superficial tangential laceration with no evidence of fracture; (2) bony depression with compression of the S.L.S. or of the lacunae, without injury to its walls; and (3) penetrating or in-and-out wounds, with the entrance and exit wounds on opposite sides of the midline and close to it.

Operation

It is not necessary to give detailed reports of each operation, but treatment varied from simple excision of the wound edges to a more elaborate operation involving removal of damaged bone, brain tissue, and foreign bodies. In all cases, except one in which a drain was left *in situ* for two days, the wounds were closed in two layers with closure of the dura. Full courses of penicillin and sulphathiazole were given as a routine.

In the description of the operation specific mention of the S.L.S. was made in five cases. In each case the impression gained was that the sinus remained patent, which corresponds to the description given by Gordon Holmes and Sargent, whose series of cases was larger and who had the opportunity of performing post-mortem examinations in some cases. At necropsy they usually found a thrombus of the S.L.S., but in view of the presence of trabeculae within its walls they thought that probably the whole lumen was not obstructed. They also described a case in which injury lay to one side of the midline, with thrombosis limited to the lateral lacunae beneath it.

The superficial cortical veins which enter the sinus in the region of the wound were found to be swollen and firm, and could not be emptied by pressure. The area of cortex drained by these veins was swollen and firm, with flattened convolutions.

Examination

Of the 11 cases five had signs involving both lower limbs only, four had involvement of both lower limbs and one upper limb, and two had involvement of all four limbs.

Motor Symptoms.—There was a loss of power in all cases, varying from a slight diminution to complete paralysis. The distribution of the weakness was constant in that in the lower limbs the distal segments were affected to a greater degree than the proximal, and in the upper limbs the opposite was the case. A typical case was that in which there was no movement of either leg below the knee, although power at the hips was such that both legs could be raised from the bed. In another case there was a complete paralysis of both lower limbs, with paralysis of the right upper arm; and in a third case there was a paralysis of both legs, with reduction of power, complete in the left upper limb and affecting all the joints of the right upper limb, particularly the shoulder.

All cases showed an increase in tone varying from a slight degree to a marked spasticity. This rigidity was typical again in that it appeared in each case almost immediately, was maximal at the start, and then showed a progressive improvement *pari passu* with recovery of function. As would be expected in this clinical picture of a spastic paresis, the reflexes in the affected limbs were increased, the plantar responses were extensor in seven cases, and there was ankle clonus in at least four.

Sensory Symptoms.—Only two cases showed no sensory impairment; the others showed, typically, impairment of postural sensibility and loss of tactile discrimination and localization. Subjective numbness and paraesthesia also occurred in two cases. There was loss of postural sensibility in eight cases; in seven of these it was the toes that were affected, in three the fingers, and in one case all the joints of one arm. The duration of the symptoms depended on the degree of injury.

In one case with a depression of the inner table just to the left of the midline for a distance of about 0.5 cm. symptoms consisted of impairment of joint sense in the toes of both feet and some diminution to light touch and pin-prick on the right side below the ankle and on the left on the outer border of the foot. At operation it was found that a small bone fragment had pierced the dura and was embedded in the top of the sensory cortex. It was removed, and eight days later there was gross diminution to light touch over both feet and loss of joint sense in the toes and fingers of both limbs. Joint sense at the knees appeared normal. Four days later sensory symptoms were normal except for slight diminution to light touch over the outer border of the left foot, and after a period of re-education in walking the patient appeared quite normal, with no physical signs. In more severe cases, however, loss of postural sensibility in the toes remained to add to the difficulty experienced in walking.

Lumbar Puncture.—This was performed in six cases, but only as a post-operative measure. The pressure was raised to above normal limits in only two cases, and in these it fell to normal within three and 14 days. This latter case, in fact, had a penetrating wound in the right mid-parietal region with in-driven bone fragments, and was the most severe case of cerebral injury in the series.

Urinary Disturbance.—Only two cases had any urinary trouble; one had a very mild degree of incontinence lasting a few days, and the other had a more prolonged period lasting several weeks.

Epileptic Attacks.—One case had a single focal epileptic attack which lasted for about 15 minutes on the day after injury and consisted mainly of flexion movements limited to the right fingers and arm. None of the cases have had any epileptic attacks for the four years for which they have been followed up.

Follow-up

Ten cases have been successfully followed up over the last four years. The only case lost sight of was one with very mild symptoms following a simple scalp laceration, and he was symptom-free six months after his injury. All the others had bony injury of varying degrees, and only two of these appear to be quite free from symptoms. One wrote in May, 1948, that he was "very well and quite normal in every way." The other has spent some time in prison for petty larceny and is considered physically fit by the authorities.

Thus while only two patients can be considered quite fit, seven of the 11 are able to earn their own living in some kind of work. One has a light job, five days a week, as a battery attendant. He is quite active, but one foot requires a

calliper splint and the other, he writes, "gets stuck occasionally." He also suffers from headaches and is rather forgetful. He had a scalp laceration in the right parietal region running over the vertex and there was a small in-driven metal foreign body that was removed without trouble. His condition now appears to be stationary.

Another man has his own small business as a book-seller. He had a severe injury with a midline laceration and a depressed comminuted fracture with penetration of the dura. His recovery was slow but steady; he can now walk unaided, but finds it difficult to tackle inclines owing to some spasticity of his foot. He also complains that if he puts his left foot down suddenly he gets a sharp pain as if he had trodden on a spike.

Another man has a sedentary job as an electrical-instrument maker, and yet another has a like job with the Ministry of Supply. The former stated in January, 1947, that he could get about alone, but that he needed a stick in wet or slippery weather. He could move his toes freely up and down, but had not got normal easy movement in his ankle or knee.

Of the four who are still incapacitated two had penetrating wounds and two had severe depressed comminuted fractures. They differ from the others only in degree, their disability being due to an inability to walk unaided owing to weakness and spasticity of the lower limbs. One of these cases (Case 6) may here be summarized, as it well illustrates the march of events.

Report of Typical Case

Aug. 14, 1944.—Patient wounded by mortar bomb. Deep laceration of scalp, no obvious fracture. Comatose.

Aug. 15.—Conscious; dysphasic; responds to name and to pin-prick. Right arm, complete spastic paralysis. Legs: complete spastic paralysis, left more spastic than right; ankle clonus; extensor plantars.

Aug. 16.—Conscious; dysphasic. Right arm, spastic paralysis. Legs: complete spastic paralysis; extensor plantars. X-ray report: "An oval depressed fracture with much comminution of the depressed portion lying up alongside the midline in the mid-parietal region on the left side. From the lower part of the 5-cm. depression a fissured fracture runs downward on, I think, the left side of the skull to terminate in the roof of the orbit. Not much separation of the edges." **Operation:**—Removal of damaged bone together with fragments that had penetrated the dura and brain. Clot and necrotic brain sucked away and wound closed.

Sept. 6.—Very mild nominal dysphasia. Gives a clear account of his injury. Right arm: tone flaccid, with some finger movements and rotation of the elbow only. Posture sense impaired in the fingers. Legs: power good on the left except for dorsiflexion of the foot, which cannot be performed; on the right he can draw his leg up but cannot move the toes and cannot raise his leg off the bed; tone flaccid; ankle clonus; plantars equivocal.

Sept. 23.—Alert. Movements of right fingers, elbow, and shoulder returning. Movement improved in right leg.

Sept. 1, 1945.—Walking, but a tendency to fall.

Feb. 12, 1948.—Right arm: floppier than left; full range of active and passive movements, but these are slower and weaker than normal. Gripping of right hand is slow, and opening of hand is associated with flexion of wrist. No discrete finger movements possible. Falling away of outstretched right fingers, and wrist. Legs: both legs "floppy," right more than left; he cannot evert his right foot and weakness of eversion of the left. Plantars extensor. Bilateral knee and ankle clonus. Loss of position sense in toes and inner three fingers of right hand and diminution of tactile discrimination at the ulnar border of right hand and wrist. He is reported as being a co-operative man who is learning to use his weak hand well and hopes to get placed eventually in a carpenter's shop.

In this case it was a full year before the patient was able to walk. The fact that he made such a good recovery was largely due to his own determination, reflected in his desire to perform work that required the use of his injured hand.

Discussion

A study of this series reveals that there is little to be added to the critical study of a series of similar cases made by Gordon Holmes and Sargent after the 1914-18 war.

The syndrome consists of a spastic paresis of characteristic distribution affecting one or more limbs and associated with cortical sensory loss in the same region. This clinical picture is the result of injuries in the region of the superior longitudinal sinus, and is remarkable particularly for the rapid, in fact, almost instantaneous, onset of the spasticity which accompanies the paralysis. This is especially emphasized in the present group of cases, for, owing to the rapidity with which cases were evacuated in this war, they were often in the hands of a neurosurgical team a few hours after injury. In addition, the injuries themselves were not of great severity in some cases, and consciousness was retained and a clear account of the injury and its effects could be obtained.

One man, for example, stated that a mortar bomb fell five yards (4.57 metres) away from him on the other side of a wall and that he was struck by fragments. He fell to his knees and could not get up. He was flown to England and was in a neurosurgical unit within eight hours. On examination he showed a very typical picture with no movement of either leg below the knee, although he could raise both legs off the bed. There was hyperaesthesia to light touch and pin-prick on the left leg below the knee and on the dorsum of the right foot. Reflexes were brisk and equal and there was ankle clonus with indefinite plantar responses. Loss of position sense occurred in the toes of both feet. X-ray examination revealed a metal foreign body situated just above the midline at the midpoint between theinion and nasion. Beneath there was a depression of the inner table for a distance of about 3 cm., the most marked depression measuring about 4 mm. The depressed bone was rongeur'd away, leaving a bone defect down the centre of which was running the longitudinal sinus, which appeared patent. He made a good recovery from the operation, and twelve days later the first flicker of returning power in the right toes was noted. His progress was slow, but a month later he was able to walk with assistance. His right foot recovered by the end of six months, but his left foot made no progress and was eventually fitted with a calliper. Two years later he was working and reported only occasional periods when his right toes "got stuck."

Another man sustained a tangential scalp wound while attacking a house. He fell down, but did not lose consciousness, and was able to crawl to cover. His complaint at that time was that his legs "felt heavy." The fingers of his right hand were also affected, and he complained later of transient attacks of blindness. The scalp wound ran from the left post-parietal region across the vertex to the right parietal region with depression of both tables extending across the mid-parietal region, the maximal depression being directly over the longitudinal sinus. This man made a steady recovery to full health.

These two cases illustrate the following points: (1) a relatively mild injury with no loss of consciousness; (2) the immediate onset of weakness and spasticity in the lower limbs; (3) the presence of bony depression in the immediate region of the longitudinal sinus; and (4) the slow and steady recovery over a long period, although in the second of these cases the depressed fracture was not elevated.

According to Gordon Holmes and Sargent the most striking pathological feature of these injuries is the firm swollen cortical veins which cannot be emptied by pressure, and the oedema of the area of cortex that they drain. Microscopically, there is oedema of the affected area, which is more prominent in the white than in the grey matter.

Minute haemorrhages occur in the grey and white matter chiefly in proximity to the wound. The nerve cells in the affected areas show pronounced changes and are greatly swollen and in advanced chromatolysis.

It is thought that this clinical picture results from the situation of the longitudinal sinus near the site of the injury. The sinus undergoes some degree of thrombosis which causes the oedema and produces the associated pathological changes in the cerebral cortex.

Thrombosis is the natural response of a large vessel of this type to trauma in its vicinity, and it is possible that it occurs independently of changes in the cortex. For although the sinus was only specifically mentioned at operation in five of these cases, the impression gained was that it remained patent owing to the presence of trabeculae within its lumen.

Lumbar puncture was not performed before operation, but the pressure was not consistently high when it was done post-operatively. Headache was not a common symptom, and in fact only one man complained of it specifically. Neither did any case show changes in the optic fundi compatible with a persistently raised C.S.F. pressure, although this would depend to some extent on the site of the thrombus within the sinus.

Wounds of varying severity in this situation cause similar symptoms, differing from each other only in degree. For example, Case 1 sustained a scalp wound with no bony injury. Symptoms were limited to a slight loss of power and some subjective numbness in the left foot which passed off in five days. In the cases previously cited the symptoms persisted over years.

None of these cases showed the initial period of flaccidity which usually occurs in cases of cerebral damage, whether due to trauma or to vascular catastrophe, and which is thought to be due to shock. This persists normally in such cases for a period of about 10 days, and only then does spasticity begin to appear. Indeed, the very feature of these cases is the immediate appearance of spasticity.

Case 11 is interesting in this respect. This man sustained a penetrating injury close to the midline in the left parietal region. He presented a rather mixed picture of right hemiplegia, with a spastic paresis of the lower limbs. He had a right focal epileptic attack on the day following injury confined to his hand and arm. Operation involved removal of damaged brain tissue and of in-driven bone fragments in the left parietal region. He made a good recovery from a severe operation, and two days afterwards showed the following signs: complete flaccid paralysis of the right arm, and a flaccid paralysis of both legs, complete on the right and almost complete on the left. He showed, in addition, loss of joint sense of the ankles and toes and an extensor plantar response.

Eleven days after operation the following signs were observed: slight spasticity of the right upper limb with some movement now possible at the elbow and slight dorsiflexion and palmar flexion at the wrist. Grip good, but some difficulty in extension of the fourth and fifth fingers. In the lower limbs tone was increased on both sides, right slightly more than left. Power was improving in the left leg, which could be held off the bed and flexed at the knee; dorsiflexion and plantar flexion were just present and he could move the toes slightly on this side. On the right, paralysis persisted except for slight movement at the hip. Ankle clonus was ill-sustained and the right plantar was extensor. Three years later he was able to get about with the aid of sticks in wet and slippery weather and was earning his living. He considered that improvement was still continuing.

This case showed a stage of flaccidity occurring after operation, but eleven days later the picture of spasticity had again become apparent. It does seem, therefore, that the site of the injury in close proximity to the superior longitudinal sinus is responsible for this clinical picture; but

this does not explain why spasticity occurs at once, and indeed its occurrence is so immediate that it must be related directly to the injury rather than to the secondary pathological changes following a sinus thrombosis. In cases where operative procedure was necessarily severe a stage of shock and flaccid paresis did appear, but ten days or so after operation spasticity had again appeared, often together with the first signs of recovery.

Recovery begins early and continues for a considerable time—several years at least. Its degree depends upon the degree of injury, and if this is severe spasticity and weakness remain and recovery depends upon how much this can be overcome by re-education in walking and the use of appliances. The main difficulty that these patients experience is the negotiation of uneven surfaces and inclines that require the presence of unimpaired postural sensibility in the toes and the ability to dorsiflex and plantar-flex the foot accurately. In the early stages of recovery the gait may be likened to that of a patient suffering from Little's disease, but most cases appear to progress enough to afford adequate movement at the hips and knees, and the residual disability is confined in these cases to the feet and ankles.

Furthermore, although the series is small, the presence of other symptoms often associated with cranial injury do not seem to be of common occurrence—that is, such symptoms as headache, dizziness, or epileptiform attacks.

Summary

A series of cases of injury in the region of the superior longitudinal sinus is presented.

The clinical picture is described and the pathology briefly discussed.

Particular attention has been paid to the clinical progress of the cases and their condition up to four years after injury.

The very early occurrence of spasticity after the injury is also emphasized.

I should like to thank Mr. Wylie McKissock for permission to study and follow up these cases, and Dr. J. E. S. Lloyd for permission to publish this paper. I should also like to thank Miss Montgomery for her help in contacting the cases.

Under the National Insurance (Overlapping Benefits) Provisional Regulations, 1948, certain reductions are made in the rate of benefit payable to in-patients who are maintained free of charge in hospital. These provisions have thrown into relief the question of the extent to which hospitals should provide their patients with the non-medical necessities of life and with minor luxuries. There are certain articles which the Minister considers should be provided as a matter of course for all patients who do not prefer to provide their own—such things as soap, tooth paste or powder, razor blades, sanitary towels or their equivalent, the services of a barber, a reasonable supply of notepaper on request, and a selection of newspapers and magazines in the wards (though not an individual issue). Other articles may be supplied to patients on loan—e.g., towels, hairbrushes and combs, and, where necessary, night and day clothing. It is not easy to distinguish between essentials of this kind and minor luxuries, in other words, between what should be provided at the expense of the Exchequer and what may be provided from the commiserate free money, and the Minister leaves committees to exercise their discretion in determining this issue. He considers that hospitals should not provide as a charge on patients such things as cosmetics, permanent waving, postage stamps, etc. Where patients remain in hospital for long periods, the range of articles to be provided at the Exchequer cost should be somewhat

A CASE OF BILATERAL PHAEOCHROMOCYTOMA

BY

T. M. REID, F.R.C.S.Ed.

Honorary Surgeon

AND

R. SALM, M.D., L.R.C.P.&S.Ed.

Pathologist

Camborne-Redruth Miners' and General Hospital

Phaeochromocytomata are rare enough to warrant the recording of an additional case.

Case Report

The patient, a married woman aged 40, was admitted in October, 1946, complaining of generalized throbbing headaches for the past ten years. These were present by day and by night, but had increased in severity during the past two years. Sometimes after exertion or on stooping the headaches became very severe, spreading from the temporal and infraorbital regions to the vertex and occiput. These attacks lasted for two to three minutes, but the patient emphasized that she was never completely free from headaches. On moderate exertion she soon became breathless and suffered from palpitations. Weakness and loss of weight had increased, particularly during the three weeks before her admission. Her past history had been uneventful. Her family history was very interesting.

Her father died at 46 of Addison's disease, though its cause (atrophy, tuberculous infection, chromaffinoma) is debatable. Of six other siblings, one brother died at 28 of diabetes, while one sister died at 29 of an obscure bone disease. She was apparently healthy up to the age of 14, when she started to "shrink." At the time of her death her body was about the size of a child of 4. The condition was regarded as that of an "achondroplastic dwarf."

Physical Examination.—The patient looked very much older than her age. Pigmentations were not present on skin or mucous membranes. There were visible arterial pulsations in the anterior cervical triangles and in the suprasternal notch, and the apex beat was forcible. The pulse was regular, but there was a tachycardia of 140. The blood pressure was raised to 227/128. The blood urea was 65 mg. per 100 ml. Hyaline casts were constantly found in the urinary sediment, and a moderately large tumour which did not move with respiration could be felt in the right lower abdomen. Both fundi of the eyes showed sparse, scattered, superficial retinal haemorrhages of moderate size in the paracentral areas. One vein below the left optic disk appeared to be compressed by the overlying artery.

X-ray Examination.—The ascending pyelogram showed that the right kidney corresponded to the tumour felt by abdominal palpation and was found to be rotated forward, outward, and displaced downwards. Both kidneys were secreting. The left kidney was normal in appearance and position. Above the right kidney there was a dense shadow, and a new growth of the right adrenal gland was thought to be most likely.

A presumptive diagnosis of chromaffinoma of the right adrenal gland was made and operation was decided upon. Under N₂O-ether anaesthesia the right lumbar region was explored and a large adrenal tumour removed. During the operation it was noted that both pupils became maximally dilated as soon as the tumour was handled. Post-operatively the patient was immediately treated for shock, adrenaline was given, but in spite of this she did not rally and death occurred within 24 hours.

At necropsy the left adrenal gland appeared to be also grossly enlarged, weighing 40 g. In parts the usual shape of an adrenal gland was still recognizable, but a large round tumour mass occupied the central portion of the gland. On sectioning, normal yellow cortical tissue was only sporadically recognizable. For the greater part the whole organ and round mass consisted of soft yellowish or dark brown jelly-like material. The right

adrenal gland, removed at operation, weighed 325 g and consisted of two distinct masses, held together by a flat, broad pedicle. The smaller of the two, still resembling in shape an adrenal gland, measured $6\frac{1}{2}$ by 4 by $3\frac{1}{2}$ cm. The larger mass was oval, measuring $10\frac{1}{2}$ cm across and $7\frac{1}{2}$ cm in width. The tumour was surrounded by a thin fibrous capsule and was moderately firm. On sectioning the cut surfaces were whitish or yellowish brown in colour, but there were many areas of haemorrhagic infiltration as well as areas of cystic degeneration.

Microscopically both tumours appeared to be composed of strands and masses of fairly large somewhat pleomorphic cells possessing an oval or round vesicular nucleus displaying a delicate chromatin network and exhibiting a distinct nucleolus surrounded by a fair rim of basophil cytoplasm, and often forming syncytium-like complexes. They were supported by scanty stroma and often surrounded blood sinusoids. At the periphery the tumour cells occasionally resembled normal adrenal medullary tissue. They stained dark brown after fixation in potassium bichromate solution. The diagnosis was chromaffinoma.

Discussion

Phaeochromocytoma, or chromaffinoma, is a comparatively rare tumour. Up to 1946 about 176 had been recorded, of which only 47 showed hormonal activity (Calkins and Howard, 1947). Among these there were 16 bilateral growths (Mackeith, 1944), so that the present case is probably the 17th*. Every year several new cases are recorded (Espersen and Dahl-Iversen, 1946; Washington *et al.*, 1946; Blacklock *et al.*, 1947; Brunschwig, 1947; Goldenberg *et al.*, 1947; Gutmann, 1947; Kipke, 1947; Mandl, 1947; Schneider, 1947; Spalding, 1947). The symptoms, though essentially those of hypertension due to an excess of adrenaline production, may vary, and some authors distinguish four clinical groups: (1) paroxysmal hypertension, (2) persistent hypertension, (3) asymptomatic, and (4) malignant. A fifth and very rare manifestation is Addison's disease due to compression of the adrenal cortex by the new growth. In addition to the signs and symptoms of hypertension, including haemorrhages in the eyes and partial or complete compression of the retinal veins by their corresponding arteries, anaemia, loss of weight, lassitude, insomnia, fibrillation, and hyperglycaemia and glycosuria have been observed.

Chromaffin tumours may arise from chromaffin tissue throughout the body, but do not appear to give rise to clinical symptoms unless situated in or in close proximity to the adrenal glands (Mackeith, 1944).

Apart from the history and abdominal palpation, x-ray examination is of help in diagnosis. Tomography revealed the presence of a growth in one case (Mandl, 1947). Perirenal insufflation of air is recommended by several authors. A rise of the serum potassium during hypertensive paroxysms was described by Blacklock *et al.* (1947), while others found an increased content of adrenaline during the attacks (Beer *et al.*, 1937; Strombeck and Hedberg, 1939).

Recently two new tests have been devised which may prove most helpful in diagnosing the condition. Goldenberg *et al.* (1947) postulated that in a case in which hypertension is due to an increased amount of adrenaline it will be abolished or significantly decreased by the intravenous administration of adrenolytic compounds. But if hypertension is due to any other cause it will persist. The two adrenolytic benzodioxanes they employed 933 F, piperidylmethyl benzodioxane; and 1164 F, 2,4-dimethyl-piperidylmethyl benzodioxane were injected in a dosage of 0.2-0.25 mg per kg of body weight, and proved their assumption on sight. The injections were followed by a fall in blood

pressure of about 50 mm, which effect lasted for about 15 minutes—a reaction which proved to be specific for an increase of adrenaline in the circulation.

The second test was developed by Roth and Kvale (1945), based on experiments by Hyman and Mencher (1943), who also claim that their test is specific for the condition. The intravenous injection of 0.025-0.05 mg of histamine in 0.025-0.05 ml of saline into patients suffering from a chromaffinoma was followed immediately by a rise in blood pressure of about 100 mm or more, accompanied by the subjective sensations of a typical attack of hypertension. Though one might be tempted to explain this phenomenon as the reaction of the body to a vasodilator, this is apparently not the mechanism, as dilatation of vessels as such does not produce a similar reaction. Hyman and Mencher's theory is that the drug exerts an immediate action on the tumour cells, causing them to shed their hormone into the blood stream.

Up to date no medical treatment of the condition is available, unless the observation by Espersen and Dahl-Iversen (1946) can be corroborated. They treated one of their cases pre-operatively with methylthiouracil, which resulted in complete disappearance of the paroxysmal attacks of hypertension.

The new growth has been attacked over 50 times, and in many cases successfully, by surgical intervention. The most critical period is the first 24 hours after operation. Many substances have been advocated to combat the ensuing shock, of which adrenaline in large doses proved the most successful (Biskind *et al.*, 1941).

Calkins and Howard (1947) described the first two cases of familial bilateral phaeochromocytoma, occurring in a woman and her niece. They were of the opinion that there is every likelihood that the mother of the latter also died of the same disease. A remarkable incidence of goitre was shown to exist in this family. In this connexion it may be stressed that the family of our patient also showed evidence of endocrine imbalance, but none of its members suffered from thyrotoxicosis.

We gratefully acknowledge our indebtedness to our colleagues, Drs Hale, Hair, and Heath, for permission to make use of their case notes.

The Minister of Health is considering the question of the recruitment and training of matrons and assistant matrons in homes for old or infirm people provided by local authorities and voluntary organizations under the National Assistance Act, 1948. The Ministry announces that the National Old People's Welfare Committee will hold a course on Sept. 11-17 for training existing staff and with a view to selecting suitable matrons with whom future students might be placed for training. Inquiries should be made before July 5 to the secretary, National Old People's Welfare Committee, 26 Bedford Square, London, W.C.1.

*A further case of bilateral chromaffinoma, occurring in a child was demonstrated by Dr H. S. Barr at a meeting of the Association of Clinical Pathologists held at St. Mary's Hospital on Jan. 23 and 24, 1945.

SPONTANEOUS CIRCUMRENAL HAEMATOMA

A REVIEW AND REPORT OF TWO CASES

BY

K. WHITTLE MARTIN, F.R.C.S.

Resident Surgical Officer and Surgical Registrar, Worthing Hospital

The term "spontaneous circumrenal haematoma" is self-explanatory and excludes, by definition, cases of traumatic origin. The condition is said to be a rare one, though I have had to deal with two cases in the past nine years. These two cases and a short review of the subject are thought to be worth publishing, as no mention is made of the condition in most of the standard surgical textbooks, and no description of it had appeared in any English journal until that of Heritage in 1934. The condition is referred to by Hamilton Bailey (1944) and in American papers under the title of spontaneous perirenal haematoma. At risk of seeming pedantic, however, the Graeco-Roman bastardy of the word "perirenal" should condemn it. The condition is probably not as rare as the literature would suggest; it may possibly be the underlying lesion in such labels as "retroperitoneal sarcoma" and "retroperitoneal haematoma of obscure aetiology."

Case 1

A youth aged 18 was suddenly taken ill at sea with abdominal pain and vomiting on Nov. 14, 1945. There was no history of trauma. Next morning his condition was worse. He had a furred tongue and a weak thready pulse of 130; his temperature was 103° F. (39.4° C.). There was extreme tenderness and rigidity in the right loin and right iliac fossa. Examination of the urine, including centrifugalization and microscopy, was negative.

A diagnosis of retrocaecal appendicitis with generalized peritonitis was made; he was shipped ashore and admitted to the Calvary Hospital, Hobart, Tasmania. He was seen by two surgeons, who agreed with the diagnosis, and immediate operation was undertaken.

At operation the appendix was normal, but a large retroperitoneal haematoma, which appeared to surround the kidney, was found in the right paracolic gutter. The incision was extended and the swelling was being explored further when the anaesthetist reported that the patient was *in extremis* and the abdomen had to be quickly closed. He was given a blood transfusion of 4 pints (2.2 litres) and his condition improved considerably. Ten hours after the first operation the wound was reopened. This approach, rather than a lumbar incision, was chosen to enable the presence of a left kidney and its condition to be ascertained. The ascending colon was mobilized, and after mopping out blood clot a transperitoneal nephrectomy was carried out. After this operation he made a rapid and uninterrupted recovery.

Pathological Report.—"The kidney is lobulated, resembling the foetal type, with dilated pelvis and calices. No visible inflammatory reaction in the pelvic cavity. A haemorrhagic area over the hilum shows only a layer of tissue between the pelvis and the exterior. Sections show widespread interstitial nephritis, with areas of small round-cell infiltration scattered through the renal tissue. At the site of haemorrhage there is complete replacement of the renal tissue by inflammatory scar tissue."

Pyelograms, taken two and six months after operation, showed a large left kidney and large pelvis with good secretion. Now, three years after, the patient is perfectly fit and still serving as a regular officer in one of the armed Forces.

Comment.—The points of interest are: (1) this was a case of spontaneous circumrenal haemorrhage, probably secondary to a congenital hydronephrosis in a foetal-type kidney;

(2) it presented as an acute surgical emergency, and was diagnosed by three surgeons as acute appendicitis with generalized peritonitis; (3) the urine contained no red blood cells; and (4) uninterrupted recovery followed nephrectomy.

Case 2

A man aged 35 was admitted to Worthing Hospital on June 21, 1948, complaining of abdominal pain and backache for 24 hours. The pain seemed to come from the right loin and was maximal in the right iliac fossa. There had been no vomiting and no central pain, but his abdomen felt distended. Bowels and micturition were normal. He had had amoebic dysentery in 1942, with recurrences in March and September, 1943. There was no history of recent trauma.

On examination he was obviously ill and in pain. His temperature was 100° F. (37.8° C.), and pulse 92. The tongue was furred. Localized tenderness and guarding were present in the right iliac fossa, over McBurney's point and extending up into the loin. There was guarding of the lumbar muscles, but no abdominal rigidity. Considerable meteorism was noted. The liver was not enlarged, and neither kidney was palpable. Peristaltic sounds were normal. Rectal examination revealed no tenderness. The heart sounds were normal. The blood pressure was 150/95. An occasional leucocyte and some ammonium urate crystals were found in the urine, the pH of which was 6. No red blood cells or casts were seen. There was no growth on culture for 24 hours. A blood count showed: haemoglobin, 80%; red cells, 3,610,000; colour index, 1.11; white cells, 14,800 (90% polymorphs); blood urea, 46 mg. per 100 ml. Amoebae were not seen in one specimen of faeces. Two hours later his condition was worse and operation was advised. The pre-operative diagnosis was retrocaecal appendicitis, ? amoebic perityphilitis.

Operation.—Through a right paramedian incision I found that the caecum was ballooned and the small bowel distended with gas. The appendix was normal. A large retroperitoneal haematoma involved the posterior aspect of the caecum and ascending colon. It filled the right paracolic gutter, extended over the brim of the pelvis, and seemed to originate from the kidney, which was large but smooth. There was no evidence of amoebic colitis. The abdomen was closed. The anaesthetist noted that the blood pressure was 180/100. This hypertension persisted post-operatively.

Post-operative Course.—This was marked by progressive vomiting and abdominal distension. His blood pressure remained high. He developed a classical adynamic or neurogenic ileus, which failed to respond to continuous gastric suction and intravenous therapy. His condition slowly but inexorably deteriorated until death supervened on the eleventh post-operative day.

Necropsy.—A large unorganized clot surrounded the right kidney and stripped up the peritoneum. Both kidneys and suprarenals appeared normal. There was no evidence of active amoebic disease, and the liver was normal.

Microscopical Report (Dr. Standish).—"There is no microscopical evidence of haemorrhage in the suprarenals, and their vessels show no evidence of either endarteritis or polyarteritis nodosa. The surrounding blood clot shows a very early stage of organization, but no inflammatory change. There is no evidence of the cause of the haemorrhage either in the suprarenal or in the clot, itself."

Comment.—(1) The hypertension found at operation and afterwards was an interesting phenomenon and one which has not, so far as can be ascertained, been noted before in the literature. The patient's general practitioner, Dr. Shepherd, told me that he had found the blood pressure normal at several previous examinations. The cause of this is presumably compression of the renal parenchyma by the clot, and is analogous to the hypertension produced experimentally by Page (1939) and Graef and Page (1940). These workers were able to produce a sustained hypertension in dogs from perinephric scarring by silk or from compression of the kidneys by wrapping "cellophane" round them.

(2) The cause of death was adynamic ileus, due again, presumably, to irritation of the aortico-renal plexus by clot. I was satisfied at necropsy that there was no mechanical obstruction to the second part of the duodenum by the haematoma itself—an explanation which had been suggested. Some degree of meteorism is, of course, common after nephrectomy. It is my impression that a greater degree of ileus is found after a right nephrectomy than after a left; but this is only an impression, and I am not aware that the matter has been investigated.

Discussion

Aetiology

Polkey and Vynalek (1933), of Chicago, have written the fullest review of the literature up to 1933 and collected 178 cases, mostly from Continental writers. They suggested that "sudden renal congestion" might explain some of the spontaneous cases in which no cause was discovered. In experiments on dogs they ligated the renal vein with silk thread and found subcapsular haemorrhage in 33%, extracapsular haematoma in 42.8%, and some degree of parenchymal haemorrhage in 100%.

I have found a further 13 cases reported in the literature in the last 15 years. The pre-operative or clinical diagnoses of these cases, together with those of my own two, and the stated causes and results of treatment, are shown in the accompanying Table.

Spontaneous circumrenal haematoma must be regarded as a symptom-complex or complication and not as a disease entity. It follows that the lesions responsible for it are numerous. They fall into three main groups—renal, extra-renal, and the blood dyscrasias.

Group 1: Lesions of the Kidney and Suprarenal Gland.—A lesion of the kidney or suprarenal accounts for about 60% of cases. Nearly every lesion affecting these organs has been reported—renal and suprarenal cysts and tumours, chronic nephritis, hydronephrosis, aneurysm of the renal artery, lithiasis, tuberculosis, and thrombosis of the renal vein. Usually the haemorrhage is the precipitating symptom, with no previous history pointing to renal disease. Thus in one of Heritage's cases it was only with difficulty and after microscopical examination that "ghost cells" of a haemorrhagic and necrosed neoplasm were found in the clot.

Group 2: Extrarenal Retroperitoneal Lesions.—Included in this group are such differing conditions as perinephritis, arteriosclerosis, aneurysm of the abdominal aorta, and hypertension. One case was associated with periarthritis nodosa.

Group 3: The Blood Dyscrasias.—Haemophilia, polycythaemia, leukaemia, scurvy, thrombocytopenic purpura, and Hodgkin's disease have all been reported.

Clinical Course

Clinically one must distinguish between the acute and the chronic form of the disease. The acute form is by far the more common. The onset is sudden and dramatic and presents as an acute surgical abdomen. There may be no history suggesting renal disease. The classical findings

are the triad of pain, a renal tumour, and signs of internal haemorrhage (Lenk, 1909), but these are seldom all present. The muscular rigidity usually precludes the palpation of a renal tumour in the acute form of the disease. Pyrexia is due to blood absorption, and pressure on the renal parenchyma may cause albuminuria or hypertension. Later, increasing abdominal distension, vomiting, and prostration confuse diagnosis and suggest the perforation of an abdominal viscus. In fact, the haematoma may perforate the peritoneum and give a clinical picture very similar to that of a "ruptured ectopic," but in a male.

A more insidious form of the disease occurs with a sense of fullness or discomfort in the affected loin. Here there is time for investigation. A renal tumour can as a rule be felt and the diagnosis is usually hydronephrosis or hypernephroma. Careful study of pyelograms, as Ekman (1946) has pointed out, will show displacement of the kidney: the direction of displacement may indicate the location of the source of the haemorrhage.

The only reported cases in which correct pre-operative diagnoses were made are described by Cibert, Vachon, and Cavailher (1942). In all these cases a tender tumour in the loin was present. The cases were of the insidious or chronic form and they all presented a similar physical sign, not previously described in the literature. This consisted of a lumbar ecchymosis, which in time tracked down to the scrotum. This ecchymosis, when present with a tumour in the loin and in the absence of trauma, is pathognomonic of spontaneous circumrenal haematoma.

Treatment

Where the condition is suspected emergency intravenous pyelography should be undertaken. It is essential to confirm the presence, and preferably the normality, of the opposite kidney. To quote the words of Cibert, Vachon, and Cavailher: "La conclusion, exprimée par tous les auteurs, découle de cette constatation: l'opération s'impose." Non-operative treatment was uniformly fatal in every published case, except one. It must be accepted, however, that the diagnosis is usually made with certainty only at operation or post mortem. Nevertheless, operation should be advised as soon as the necessary resuscitation has been undertaken, for three reasons: (1) to arrest haemorrhage and save life; (2) to prevent the side-effects of a large haematoma—meteorism, ileus, hypertension, sepsis, and possible rupture into the general peritoneal cavity; and (3) to explore what may well prove to be a malignant condition of the kidney or suprarenal gland.

In theory it might occasionally be possible, in the extra-renal type of haematoma, to clear out the clot and ligate the bleeding vessel. According to the literature this never seems to have been done. If the haematoma appears to have originated from the kidney, nephrectomy should be carried out. If bilateral renal disease is suspected or proved it might be wiser to rest content with packing or drainage. If both kidneys appear normal and no cause is apparent the best results seem to follow nephrectomy.

As the Table shows, seven out of 15 cases were subjected to nephrectomy without a death.

Table showing Cases Reported in the Last 15 Years

Author	Sex and Age	Clinical Diagnosis	Cause	Treatment	Result
Polkey and Vynalek (1933)	F. 39	Ovarian cyst	Unknown	Drainage	Recovery
Heritage (1934)	M. 51	P.D.U.	Neoplasm	Packing	
"	M. 65	P.D.U.	Suprarenal neoplasm	Laparotomy	Death
"	M. 41	Acute cholecystitis	Unknown	Drainage	
Carver (1939)	M. 43	Hydronephrosis	Hydronephrosis	Nephrectomy	Recovery
"	M. 47	"	Hypertension	Nil	Death
Elmer and Wynn (1939)	F. 46	Hypernephroma	Unknown	Nephrectomy	Recovery
Daro and Todd (1941)	M. 51	Retroperitoneal cyst	"	"	"
Cibert, Vachon and Cavailher (1942)	M. 61	Circumrenal haematoma	"	"	"
"	M. 58	"	Suprarenal cyst	"	"
"	M. 78	"	Chronic nephritis	Expectant	"
Ekman (1946)	M. 48	Appendicitis	Unknown	Laparotomy	"
"	M. 48	Hypernephroma	Hypernephroma	Nephrectomy	"
Martin	M. 18	General peritonitis	Hydronephrosis	"	"
"	M. 35	Appendicitis	Unknown	Laparotomy	Death

Summary

The condition of spontaneous circumrenal haematoma is described, with two personal case histories.

Though rare the condition is an important one to bear in mind, as it may enter into the differential diagnosis of the acute abdomen and if treated expectantly is nearly always fatal.

The aetiology and clinical course are discussed. An acute and a chronic form can be distinguished.

Treatment should consist in surgical intervention and, in most cases, nephrectomy

APLASTIC ANAEMIA FOLLOWING NEOARSPHENAMINE

BY

F. DUDLEY HART, M.D., M.R.C.P.

Assistant Physician, Westminster Hospital

AND

J. G. HUMBLE, M.R.C.S., L.R.C.P.

Haematologist, Westminster Hospital

Aplastic anaemia is a well-recognized but rare complication of organic arsenical therapy. Wintrobe (1946) states that more than 100 cases have been reported in the literature, also that less than one-half of the cases described showed complete aplasia of the marrow. Recovery after complete aplasia has been recorded, however (Wintrobe, 1946). The case described below, which exhibited anaemia, leucopenia, thrombocytopenia, and a completely aplastic marrow on sternal puncture, seems to fall into this class and to be worthy of record.

Case Report

The patient, a man aged 52, contracted primary syphilis and gonorrhoea abroad in June, 1946. He received 37 injections of neoarsphenamine and 37 of bismuth during the next nine months.

He noticed nothing abnormal until April, 1947, when he had a severe epistaxis lasting 16 hours. The red blood cells numbered less than one million. Injections were stopped, but a month later further severe nose-bleeding occurred, with the appearance of petechiae and "papules" on the arms and legs. His haemoglobin was 30%; colour index, 1; red blood cells, 1,500,000 per c.mm.; white blood cells, 3,000 per c.mm. (L. 78%, M. 1%, P. 21%); platelets, 25,000 per c.cm.; coagulation time, 14 minutes. Wassermann reaction and Kahn test were negative. The spleen was never palpated.

He was treated with iron, a fresh blood transfusion, and 10 ml. of pentnucleotide every 12 hours. He received altogether some 6 pints (3.4 litres) of fresh blood. Four days later a blood count showed: red cells, 1,670,000 per c.mm.; haemoglobin, 30%; colour index, 0.9; bleeding time, 3½ minutes; coagulation time, 6 minutes; leucocytes, 2,000 per c.mm. (L. 73%, N. 2%, E. 3%, P. 22%).

He then returned to England, and during the voyage was given 1 ml. of "hepatab" daily, 45 gr. (3 g.) of iron and potassium citrate, and 5 mg. of folic acid thrice daily. On his return he stated that he did not feel very ill, but became giddy

and tired on the least exertion. Up to this time he had had 11 blood transfusions in all, the last being on May 19. No further epistaxis had occurred, but he had noticed some oozing from his gums and he found that he bruised easily and "came out in little red spots." Previous illnesses and family history revealed nothing relevant.

He was admitted to hospital under our care on May 31. He was a very co-operative man, very pale, and obviously grossly anaemic. His skin was sallow and sunburnt. There was pronounced foetor oris; his teeth were in a bad condition, with much dental sepsis; the gums were soft and spongy, with pus oozing from them. The tongue was furred but moist. No bismuth line was present. No glands were palpable and no petechiae or bruises were seen. Over his legs and feet the skin was scaly, pigmented, and ulcerated. The blood pressure was 120/60. A soft systolic murmur was present over all areas in the praecordium. The capillary resistance test was strongly positive in three minutes at a pressure of 90 mm. Hg. Nothing abnormal was detected in the chest apart from an occasional rhonchus at the bases. The spleen was not palpable.

The pupils reacted normally to light and to accommodation. Ophthalmoscopy showed normal optic disks. No exudates were seen, though multiple large haemorrhages were present in both retinae. The central nervous system was otherwise normal.

Chart showing haemoglobin findings

The diagnosis of aplastic anaemia due to arsenical therapy was made. The haemoglobin findings are shown in the accompanying graph. Radiographs of lungs and tibiae were negative. The B.M.R. was 4%.

The patient was kept in hospital until Sept. 16, when he was discharged home. During this time his haemoglobin rose from 20% to 104%. A total of 2 pints (1.14 litres) of whole blood and 29 pints (16.5 litres) of packed red cells was given over this period. He did not react adversely to any transfusion, and over the whole period made slow but steady improvement. Penicillin was administered, 40,000 units four-hourly, for the first month, the dosage gradually being reduced over the following three months to 100,000 units twice daily. Liver extract was given by injection (hepalon) 2 ml. daily at the onset, being reduced to twice a week after two months. He also received pyridoxin 100 mg. daily, ferrous sulphate 10 gr. (0.65 g.) thrice daily, two multivitamin tablets thrice daily, and folic acid tablets (15 mg.) daily.

On Oct. 2, 14, and 27 he was readmitted for the transfusion of 2 pints (1.14 litres) of packed cells on each occasion. The condition of the skin of the feet and legs greatly improved, and the capillary resistance test, still positive on Oct. 14, became negative after this time.

Two further pints of packed cells were given on Nov. 20 and Dec. 18. It was apparent at this time that he was making steady progress, and that he was beginning to pick up on his own. He was last seen on May 31, 1948, when he was in excellent general condition. The Wassermann reaction and Kahn test were negative. Our last report, received from abroad in October, 1948, was that he was in perfect general health and had received no further treatment.

Haematological Findings.—On June 2, 1947, these were as follows: haemoglobin, 22% (3.03 g.%); red cells, 1,210,000

per cmm.; colour index, 0.9; white cells 900 per cmm (lymphocytes 80%, and neutrophil polymorphs 20%, approximately). No red cell abnormalities were noted. On June 3 the bleeding time was longer than 10 minutes the clotting time (venous blood) 11 minutes, the prothrombin time 11 seconds (normal, 8 seconds); blood platelets 3 400 per cmm, reticulocytes were not found. The blood was Group O (IV) Rhesus positive.

Table showing Results of Sternal Punctures

Date	June 3 1947	Aug 16 1947	May 21 1948
Total nucleated count	3 400 per cmm	10 200 per cmm	25 000 per cmm
Myeloblasts	—	0.4%	1.2%
Proerythrocytes	1 seen in 3 films	0.6%	0.8%
Neut. myelocyte	—	6.8%	9.2%
Neut. metamyelocytes	—	3.7%	6.6%
Neutrophils, segmented	Present	15.0%	24.2%
Eosin. myelocytes	—	1.7%	0.2%
Eosinophils	—	1.0%	0.6%
Basophil myelocytes	—	—	—
Basophils	—	—	0.2%
Lymphocytes	Present	32.6%	29.0%
Monocytes	—	3.2%	2.0%
Megakaryocytes	—	0.2%	Present—mature forms found
Haemocyto blasts	—	1.7%	0.2%
Normoblasts basophil	1 seen in 3 films	6.8%	2.6%
Normoblasts, polychromat	—	21.0%	19.8%
Normoblasts orthochromic	—	6.7%	1.0%
Myeloid erythroblast ratio	—	1.16	1.57
Mit. cellanous cells	—	0.4%	0.4%
Naked eye	A fatty fluid	A fatty fluid	Marrow particles very evident

The sternal puncture findings are presented in the accompanying Table. They show a progressive return of cellularity from a condition of almost complete aplasia.

Haematological Progress—The neutropenia persisted until May 18, 1948, when for the first time the neutrophil polymorphs amounted to more than 2 000 per cmm. Reticulocytes were not found in any numbers until Feb. 2, 1948, when they totalled 5% of 3 800 000 red blood cells per cmm (190 000 per cmm). The platelet count did not rise to normal figures until after Feb. 24, 1948, when it was 40 000 per cmm. On May 21 1948, the platelet count was normal.

Discussion

It is of interest to note that the last cell series to recover completely in the circulating blood was that of the neutrophil polymorphonuclears. Neutropenia persisted from April 1947, to May, 1948—a period of 13 months. Reticulocytes did not appear until after nine months of treatment, and platelets returned to normal only after a full 12 months. The capillary resistance test remained positive for seven months. It was felt that, of all the therapeutic agents given, penicillin and blood transfusions were the most important. The former totalled some 35 mega units, administered over a four-months period. The condition of the mouth and legs gave cause for anxiety in the early months, but about the end of the sixth month of the disease a gradual improvement became apparent.

Summary

A case of aplastic anaemia following neoarsphenamine administration is described. Depression was present in all marrow elements—a condition of almost complete aplasia. Recovery was complete after 13 months.

Wintrobe, M. M. (1946) *Clinical Hematology*. Kimpton, London.

The Ministry of Health states that hospitals may provide clothing for those "up" patients unable to provide it themselves and who are not obtaining it from other sources such as voluntary organizations. They would normally be long stay ambulant patients. The patients may retain this clothing after discharge from hospital if the hospital is satisfied that the patients need clothing and are unable to obtain it from their own resources and without help.

HISTAMINE HEADACHE*

BY

M. ESZENYI-HALASY, M.D.

(From the Neurological Department of Szent Istvan Hospital, Budapest)

Headache is the most frequent complaint encountered in medical practice. It presents no diagnostic problem; the diagnosis is made by the sufferer. But the doctor must know the cause if he is to treat the patient efficiently.

Table I classifies the forms of headache that I have treated. The present paper is concerned mainly with the type of headache due to histamine, as described by Horton in 1941.

TABLE I—Results of Treatment by Histamine

	Histamine 1 cc 1% solution	Atropine	Psychic Headache	Relaxation Headache	Alcoholic Headache	Headache associated with hypertension	Headache with Organic Disease	Total	Controls with Headache
Complete cure	29	2	2	2	1	2	2	40	10
Considerable improvement	8	1	2	1	1	1	1	16	1
Some improvement	6	2	2	0	0	0	1	11	1
No change	2	3	2	0	0	0	5	13	1
Total	45	8	8	3	2	3	10	80	10

Clinical Features and Aetiology

Vallery-Radot in 1925, Brickner-Riley in 1935, and Money in 1939 described cases of atypical migraine which seem to be similar to the histamine headache described by Horton. It was Horton, however, who first described the syndrome, made the aetiology clear, produced the same symptoms experimentally, and outlined the method of treatment.

The characteristic symptoms of histamine headache, the frequency of which is shown in Table II, are as follows: it occurs in paroxysms, is unilateral, and is confined to a circumscribed area; on the same side there is congestion of the nasal mucous membrane, attacks frequently come on at night, and the patient often rises in the morning with headache. It is neither hereditary nor familial, has no connexion with menstruation or ocular disturbances, and is unassociated with vomiting. The condition is resistant to all treatment. In these patients headache produced by the injection of histamine is of the same type as occurs spontaneously.

As to the aetiology, it must be presumed that the accumulation of histamine produces an upset in cell metabolism. This accumulation is the result either of overproduction of histamine or of the inhibition of the destructive factor. It is also possible that individual hypersensitivity plays a part in cases in which the production of histamine is normal. According to Horton, in histamine headache the symptoms are caused by dilatation and constriction of the external and common carotid arteries. On the other hand, Wolff, Schumacher, Clark, Butler, Shuterland, and Pickering have proved, on the evidence of many cases, that the internal carotid is responsible for the quality and the intensity of histamine headache, and that the dilatation of the external carotid is of decisive importance in migraine. They demonstrated with photographs, taken during headache produced by the injection of histamine: (1) the amplitude of intracranial pulsation (which is increased); (2) the

*A paper read at the International Congress of Medicine held at Budapest in September 1948.

TABLE II.—Typical Symptoms of Histamine Headache

arterial blood pressure; (3) the pressure of the cerebrospinal fluid, and (4) the degree of pulsation in the temporal artery.

Increase in the intracranial pressure reduces the pain in histamine headache by providing counter-pressure to the dilated arteries, signifying that the dilatation of these arteries plays a part in the production of this type of headache. In migraine, however, this procedure has no influence on the headache, a fact which implies that dilatation of the extracerebral arteries is the basis of the condition.

Horton noted that repeated administration of the same dose of histamine could produce a progressively diminishing headache, that is to say, the tolerance of the patient for histamine had increased. These observations led him to try desensitization. The term "desensitization" is used here in its widest sense. The desensitization is non-specific because specific hypersensitivity is not the aetiological factor and there are symptoms of neither hypersensitivity nor of allergy. But the favourable effect of a long course of small doses demonstrates that the therapeutic effect is in the nature of a desensitization.

It is accepted that, although differing greatly from adrenaline and the choline derivatives in nature and origin, histamine will probably take its place with them among the most important hormones in animal life. Dale and de Krogh have explained the role of histamine in capillary vasodilatation and the regulation of blood pressure. Later, in 1947, Emmelin and Feldberg observed that histamine was a physiological antagonist of adrenaline. So far as we know, histamine is a breakdown product of tissue proteins, which produce an acid of which histamine (β -iminazolyethylamine) is the amine. The release of this amine occurs in shock due to anaphylaxis, trauma, and other causes. The liberation of histamine may be local.

An interesting question confronts us: Why should a symmetrical system respond with pain which is asymmetrical, unilateral, and localized? It must be presumed that some unknown mechanism makes this possible. The resistance of the arteries to histamine may become less in a circumscribed region and the dilatant effect produced at this point, or some arterial lesion in this area may bring about a local liberation of histamine.

Treatment

In the neurological department of the Szent István Hospital, under Professor Lehoczky, I have treated 90 patients with histamine. They had headache of long duration—between two months and 30 years—which was resistant to all treatment and made them incapable of any work. I have followed up the cases for six months, either by personal contact or by correspondence.

I first gave each patient a test dose of 0.3 mg. of histamine subcutaneously. The local reaction appeared in the form of a red urticarial weal with a surrounding areola of vasodilatation. After several seconds flushing of the face, neck, and chest, and tachycardia occurred; a few minutes later a localized headache began in the usual site. This reaction could be reproduced exactly in all cases of histamine headache. In atypical cases a stronger dose of histamine was necessary to produce the same reaction. In ten control cases not suffering from headache the injection caused a feeble reaction or no response at all, in two cases resulting in only a mild headache, which disappeared in a few minutes.

The symptoms generally continued for from ten minutes to three or four hours. The next day I began desensitization with an injection of 0.1 mg. of histamine subcutaneously, and continued the treatment on the following day according to the reaction to the preceding dose. If the headache, tachycardia, and rise in blood pressure were too severe I reduced the dose. Tolerance increased after the first three or four injections, and I therefore progressively increased the daily dose to 0.2 mg. There are recorded in the literature intradermal and intravenous treatments with various solutions of histamine in extremely high dosage for periods of two to three months, but with my method I obtained the same results in less time (Table I).

Case Reports

The following cases illustrate the course of treatment.

Case 1.—A woman aged 48, suffering from headache for thirty years, which was always confined to the frontal region on the right side. She had had several courses of treatment without result. After x-ray examination the headache was attributed to osteitis of the frontal bone. The patient came to me in a state of depression and was unable to work because of the very severe headache. After the first four injections the headache ceased. She received ten further injections. Five months after the treatment was finished the headache had not returned.

Case 2.—A woman of 24, suffering for six years from headache which was becoming more and more severe. It was always situated in the right temporal region and on the crown. She had to get up five or six times during the night because of the headache. The attacks often occurred during the daytime, and were accompanied by nasal obstruction and watering of the eyes. At the site of the subcutaneous injection there was a local reaction. One or two minutes afterwards she experienced a headache corresponding exactly to her spontaneous attacks. After ten injections she could leave hospital. She has since informed me that she no longer suffers from headache.

Case 3.—A woman aged 49 had had headache since the birth of her son, who is now 28. This was not precisely the type of headache associated with histamine. The pain was stationary and made her incapable of work. She tried several treatments in vain and was driven to ideas of suicide. After the first five

injections she had no more headache. She received one injection a day during the next two weeks, and her previous complaints—loss of appetite, depression, fatigue and vertigo—all disappeared. She now does hard work on the land in extreme heat. She receives one injection a week and is free of symptoms.

Case 4.—A man aged 59 suffered for six years from headache in the frontal and occipital regions. The attacks began when he had finished his hard mental work and left for his week-end rest. This is headache of the "relaxation" type, such as is experienced by a priest on a Monday and by students after an examination. Haemoconcentration reduces the volume of blood, and the relaxed arterial walls are not able to resist the dilatant effect of histamine. After seven injections the patient was free of symptoms for six weeks. He was taking small doses of ergotamine tartrate during this period. The headaches then recurred, but twenty further injections completely cured him.

Comment

I have never observed any severe side-effects. The injection of histamine influences the blood pressure and the pulse for only a few minutes. I have therefore used this therapy in heart disease, hypertension, and hypotension. Palpitations occurred in the first days of treatment, but diminished during the course of desensitization. Several patients experienced a metallic or acid taste in the mouth shortly after injection, one patient had diarrhoea which lasted a week, and vomiting occurred after the first two injections administered to a patient with hyperchlorhydria. But, despite these disagreeable secondary effects, I have on more than one occasion heard the patient say, "I am a new man."

The important point of this therapy is that the patient is completely relieved of his pain at the end of treatment and requires no other remedies. I have reached the conclusion that treatment by histamine is worth while in all cases of frequent headaches of long duration.

Summary

The clinical features and possible pathogenesis of headache due to histamine are discussed. A course of treatment by injections of histamine is described. Details are given of four patients so treated.

Medical Memoranda

Unusual Case of Coronary Thrombosis

There is both clinical and pathological evidence that thrombosis occurs at the site of a previous sclerotic or atheromatous area in a coronary vessel. The event that initiates the thrombosis is, however, very variable, and in many instances may not be apparent. The following case is interesting in view of the dramatic nature of the immediate cause of the infarction.

CASE REPORT

A man aged 49 was seen at Professor Robert Platt's out-patient clinic and gave the following history. He had known for some years that he was abnormally sensitive to a wasp-sting, as he had previously developed severe generalized angioneurotic oedema immediately following a sting. Some months ago he had again been stung on the ankle and within ten minutes felt extremely ill, vomited, and had a sudden attack of diarrhoea. He perspired profusely and had agonizing precordial pain, as though there were a tight band around the chest. Simultaneously he developed severe angioneurotic oedema of the face and had a rigor. The next day the symptoms had subsided except for the precordial pain, which lasted for a further two days before disappearing; there was some fever at this time and he complained of shortness of breath. Seven weeks later he had no complaints except slight

residual dyspnoea. Physical examination revealed no abnormalities; the blood pressure was within normal limits.

A clinical diagnosis of myocardial infarction was made. This was confirmed by electrocardiography, which showed sharp inversion of the T waves in the limb Lead I and in the unipolar precordial Leads V4 and V6, the changes being typical of anterior myocardial infarction.

COMMENT

This would seem to be a case of coronary thrombosis which was precipitated by a severe immediate allergic reaction following a wasp-sting. Numerous cases have been reported previously in which thrombosis, followed by conditions causing shock and sudden fall of blood pressure. Boas (1942), in a review of immediate causes of cardiac infarction, mentions non-penetrating chest injuries, effort, emotion, allergy, cold, infectious disease, operation, and haemorrhage. Among cases classed as due to allergy, one occurred during serum sickness a week after an injection of tetanus antitoxin; one occurred six hours after an intravenous injection of typhoid vaccine; and another developed symptoms of coronary insufficiency after prophylactic pollen injections for hay-fever. Lockhart (1939) reports another case of coronary thrombosis, proved at necropsy, which occurred three hours after an intravenous injection of typhoid vaccine, death taking place one hour later.

Although no records are available of blood-pressure readings during the acute phase of the illness, it is well known that a severe anaphylactic reaction may cause a sudden fall in arterial blood pressure. Such a fall in blood pressure may have precipitated infarction in the case reported.

A Case of Curling's Ulcer

In 1842 Thomas Curling described an acute ulcer in the second part of the duodenum as a complication of extensive cutaneous burns or scalds. He stated that the ulcer was situated opposite the ampulla of Vater, and described it as small, clean-cut, and deep. Following this description cases of this condition were reported from many places in Britain, on the Continent, and in America. It was suggested that toxins were excreted in the bile, apparently on the supposition that the bile is secreted with such force as to impinge on the opposite wall of the duodenum and ignoring the fact that it is secreted only when food is in the duodenum. A more reasonable hypothesis is an infected embolus from the burnt area, though why infarction should always occur in the same area is not explained.

More recently cases have only rarely been reported. Some textbooks continue to give an adequate description of the condition, others make no mention of it, while some cast a varying degree of doubt over its very existence. Ross (1925), for example, states that "its occurrence is practically unknown and grave doubt has been cast on the statement" (of the occurrence of this complication of burns). The following case is reported to show that such an ulcer does occur, and that it is a complication of burns. It may be objected that the scalds were neither very extensive nor very severe, but an ulcer due to any other cause at the age of 6 years and in the second part of the duodenum is more improbable.

CASE REPORT

On Aug. 26, 1947, a Chinese boy aged 6 years was admitted to the District Hospital, Ipoh, with second-degree scalds from hot water on the lower part of the back of the trunk, the

perineum, and the thighs. There was a moderate degree of shock on admission. His general condition improved with suitable measures, and the scalds were cleansed and then dressed with sulphanilamide cream, and sulphanilamide tablets were given by mouth. During the next three days he had a temperature ranging between 99° and 100° F. (37.2° and 37.8° C.) and a pulse rate which on the evening of Aug. 27 suddenly rose from 90 per minute to 140. There was no vomiting or tenderness in the abdomen. The bowels did not move. The next day the bowels moved, but no blood was noticed in the stool. The pulse still remained around 130, and it was noticed that the child was a little restless. On Aug. 30, in the forenoon, he suddenly passed a very large amount of dark-coloured blood per rectum and a little later vomited a small amount of dark-coloured blood. His general condition deteriorated rapidly, and in spite of measures to replace fluid loss he died the same night.

It is now evident that the haemorrhage must have started insidiously on the evening of Aug. 27, approximately 30 hours after the injury; its insidious onset and progress passed unnoticed until the occurrence of the large melaena and haematemesis, which only then drew attention to the fact that haemorrhage was occurring somewhere high up in the intestinal tract, probably in the duodenum.

At necropsy the intestine was found to be full of blood clot, the organs were pale and exsanguinated, and an acute ulcer was present in the second part of the duodenum 2.5 cm. proximal to the ampulla of Vater on the postero-medial wall. The ulcer was circular, about 1.5 cm. in diameter, with shelving walls, and extended down to the muscular coat; in the floor of the ulcer a small eroded artery was found from which apparently the haemorrhage had come.

Curling's ulcer is probably more common than is realized; it is fair to assume that not all the cases diagnosed will be reported, and it will be diagnosed only in the event of haemorrhage, perforation, or necropsy, and presumably these do not occur in every case.

Our thanks are due to the Director, Medical Services, Federation of Malaya, and the Director, Institute for Medical Research, Kuala Lumpur, for permission to publish this case report.

A Case of Arteriovenous Aneurysm

The following case of arteriovenous aneurysm between the ascending aorta and the superior vena cava is described because of the rarity of this condition.

CASE HISTORY

A Chinese labourer aged 42 was admitted to the General Hospital, Singapore, on Aug. 22, 1947. The history given was that on the previous day at about 7 a.m., while carrying a bucket of water, he felt a sudden pain over the front of the neck; this was followed by swelling of the neck, duskiness of the face, and difficulty in breathing.

He looked very ill and presented a dramatic picture—sitting up in bed, gasping for breath, hardly able to talk, dusky over the face, neck, shoulders, and upper half of the thorax, with some swelling and induration of the soft tissues over these areas. A marked continuous thrill was felt immediately above the inner third of the right clavicle. Percussion did not reveal any enlargement of the heart. The sounds were rapid and regular, with accentuation of the second aortic. A continuous loud machinery murmur with systolic accentuation was heard over the heart and all over the chest anteriorly; it was loudest over the area of the thrill in the right supraclavicular region. This murmur disappeared when firm digital pressure was applied

over the area of the thrill. The blood pressure on the right side was 130/70, on the left side 126/70. Examination of the lungs showed some diminution of breath sounds over the right side. The inguinal lymph nodes were enlarged. There were no genital scars. No abnormality was discovered in the abdomen or the nervous system.

A diagnosis of arteriovenous aneurysm between the aorta and superior vena cava was made. Death ensued after three hours. As he was dying the dusky appearance of his face faded away.

Necropsy.—The heart was normal in size, with post-mortem clots in all the chambers. The muscle was reddish brown in colour and firm. The valves were normal and competent. Pearly-white linear scars of syphilis were present at the root of the aorta and along the arch. At the junction of the ascending and transverse portions of the arch was an aneurysmal dilatation, the sac of which measured 8 cm. in diameter, with an inlet 4 cm. in diameter (Fig. 1); it was adherent to the upper lobe of the right lung. The sac had ruptured into the upper portion of the superior vena cava (Fig. 2). All the large veins of the neck were greatly dilated. Other organs showed congestion.

COMMENT

This is a typical case of spontaneous arteriovenous aneurysm within the thorax. The perforation occurred suddenly during exertion and was followed soon after by evidence of obstruction of the superior vena cava. The thrill and murmur were characteristic of an arteriovenous

communication. The heart showed no evidence of enlargement, as the aneurysm did not involve the aortic ring. The aetiological factor was syphilis. Out of the 23,000 necropsies performed during the last twenty years in the Department of Pathology, Singapore, this is the first case of a thoracic arteriovenous aneurysm.

I am indebted to Dr. T. Balasingham for the necropsy report.

Reviews

THE NATIONAL HEALTH SERVICE

The National Health Service By Charles Hill, M.A., M.D., D.P.H., and John Woodcock (Pp 432 16s) London, Christopher Johnson 1949

This is a most welcome and opportune book which could have been produced only by people thoroughly immersed in all the complexities inherent in the new national service. It is no mere catalogue of references to clauses in the Act and regulations. In many instances the authors discuss objectively the intentions of the regulation under discussion, when these are not too clear, and the way in which the regulation is likely to work. They have also done their best under great difficulties, to bring the book right up to date. In the last two chapters they discuss the Amending Bill (now on its way through Parliament) and give the latest proposals of the Minister on how he intends to apply the findings of the Specialists' Spens Committee. There are many valuable appendices providing full particulars of the various boards, councils, and committees which are responsible for making the system work.

I think the best test of a book of this kind is whether its index is full and intelligible. I have subjected it to many trials, from which it has emerged with credit. To give just one example, I have never been clear who is responsible for choosing the doctor for the children of a family. The index referred me to page 33, where I found that this duty devolves on the mother if the children are under 16.

In spite of the speed at which much of the book has necessarily been written there are no signs of haste in its production. It is a handsome volume, well bound, and the type is excellent. All concerned with it can be heartily congratulated. It is, indeed, as described on the cover, "a book which no one working in this vast field, whether as doctor or layman, can afford to be without." To these I would add people like me who are interested observers. I prophesy many future editions of "Hill and Woodcock."

RESPIRATORY FUNCTION TESTS

L'Exploration de la Fonction Respiratoire By Jacques Arnaud, Pierre Tulou, and Robert Méngot. Preface by E. Rist. (Pp 318 54 figures 425 francs) Paris: Masson et Cie 1947

The authors first review the physiology of respiration and accepted tests of respiratory function, including bronchspirometry, and then describe a method of investigation of the function of the two lungs separately which they use as an aid in the selection of cases for collapse therapy in pulmonary tuberculosis. The 200 pages dealing with the review of physiology and accepted procedures present nothing new and are somewhat pedestrian.

The account of their own method is, however, of considerable interest. The technique consists of the occlusion of the two main bronchi in turn by an inflatable balloon on the end of a narrow catheter. They introduce the catheter under local anaesthesia through the nose, pass it blindly, if possible, through the larynx, and place the balloon in the selected main bronchus under fluoroscopic control. The patient is then placed on a couch, the anterior nares are occluded, and respirations are recorded with an ordinary Benedict-Roth recording spirometer. A first tracing is taken giving the tidal air, the vital capacity, and the oxygen-consumption for both lungs together. The balloon is then inflated to occlude one main bronchus, and the tidal air and vital capacity of the opposite lung are recorded. The authors found that in subjects whose lungs were not grossly abnormal the sum of the vital capacities of the two lungs taken separately in this way did not differ greatly from the total vital capacity. They usually included in their test a period of exercise with the legs. In patients whose pulmonary function was grossly impaired and in whom the worse lung was being examined extreme respiratory distress and asphyxia on inflating the balloon brought the test to an immediate conclusion. In cases with less severe diminution of function of the lung under examination respiration proved possible at rest, but with the added oxygen requirement of exercise the bronchial occlusion had to be terminated. In cases where dysfunction was less

severe the authors assessed the relative functions of the two lungs by their vital capacities. They claim that the investigation is technically simpler than bronchspirometry, though they admit that bronchspirometry makes possible a measurement of the relative oxygen uptake and carbon dioxide output of the two lungs which cannot be done by their method. They claim, moreover, that in the proper selection of cases of pulmonary tuberculosis for surgical treatment, unilateral bronchial occlusion mimics a state of affairs which may occur transiently after a thoracoplasty—namely, complete loss of function of the lung on the side operated upon—and that this consideration enhances the practical value of their test. Their investigation, of patients who have received collapse therapy confirm the bronchspirometric finding that a pneumothorax which has been complicated by pleural effusion and subsequent pleural thickening results in extremely severe diminution of pulmonary function, usually more than that produced by a selective apical thoracoplasty.

This account of the author's own work will be of interest to all who are concerned with methods of investigating the function of the two lungs separately.

TEACHING HEALTH

Health Teaching in Schools By Ruth E. Grout, M.P.H., Ph.D. (Pp 320 £1) Philadelphia and London: W. B. Saunders Company 1948

Positive health is the modern slogan. This means that people must know how to keep well before they contract disease. Obviously such knowledge cannot be acquired too young so health must be taught in the schools. In the "classical" school-subjects teachers know how and when to impart knowledge, having regard to the understanding and learning capacity of the children under their charge, but it is doubtful if many know how to do this in respect of health. Too often knowledge is imparted too early or too late. In this book the teacher will find first the general principles of what should be taught and then how and when the material should be transmitted to the children at various ages. Several illustrative aids which may be used are described, and various agencies outside the school whose work can illustrate and reinforce the instruction are listed. On the whole the presentation is well balanced, sex being dealt with in its appropriate place, though it may be argued that more might be done in training a healthy mind as well as a healthy body. It is true that certain social and individual adjustments are referred to, but children are capable of absorbing more than this.

Many people in this country may find this book too American, both in presentation and in matter, but there is too little literature on this subject to allow the teacher who is really anxious to shoulder his responsibilities to neglect the present volume, which is well set out, methodical, and not too long.

R G GORDON

CLINICAL CHEMISTRY

Clinical Chemistry in Practical Medicine By C. P. Sewart, M.Sc. (Dunelm), Ph.D. (Edin.), and D. M. Dunlop, M.D., F.R.C.P. Third edition (Pp 324 17s 6d) Edinburgh: E. and S. Livingstone 1949

The appearance of the third edition of this book since 1931 indicates its value to those interested in medical biochemistry. It provides a readable account of the principles underlying the biochemical tests in common use and a useful guide to their interpretation. The section on renal function tests is particularly well done, those on basal metabolic rate, carbohydrate metabolism, gastric and hepatic function tests, and other investigations follow conventional lines to give an adequate though brief account of these subjects. The chapter labelled "Miscellaneous" is perhaps too short to be of real value, it discusses acid and alkaline phosphatases on one page and vitamin and nutritional deficiencies in five pages. A few omissions were noted, such as the insulin test meal. The preference for "Van den Bergh units" rather than mg. bilirubin per 100 ml. of serum is to be regretted, and the authors do not make clear their opinion as to the significance of lactic acid in gastric contents. The appendix on technical methods is also somewhat brief, at all events from the laboratory worker's point of view.

A minor drawback to the book is the complete absence of references, an undesirable limitation in a growing subject of

this type. In fairness to the authors it should be noted that the work is intended for "the practitioner, house-physician, and senior student," but even those persons might occasionally feel the need to refer to a larger volume or to original papers on some special subject. It is suggested that this point might be considered in future editions.

N. F. MACLAGAN.

SLIT-LAMP MICROSCOPY

Ocular Signs in Slit-lamp Microscopy. By James Hamilton Doggart, M.A., M.D., F.R.C.S. (Pp. 112; 93 illustrations; of which 85 are in colour. 21s.) London: Henry Kimpton. 1949.

English ophthalmic literature has need of a small compact survey of the practical essentials of the slit-lamp biomicroscopy of the eye. The early works of Harrison Butler and the English translation of Koby's work are quite out of date and now out of print. For the advanced worker larger treatises are available, although none has originated in this country: the five-volumed *Atlas* of the French Ophthalmological Society published before the war is admirable, Berliner's two-volumed *Atlas* (New York) is good, and Vogt's monumental work (three volumes) is superb. But the junior postgraduate student has had no guide within his compass until the book under review appeared. The subject-matter includes all the essential techniques and the appearances of the normal, deformed and diseased eye. It is simply expressed in very readable form, not over-laden with detail, and comprehensively and beautifully illustrated with many original pictures; it contains a useful bibliography. The publishers have done their job well.

STEWART DUKE-ELDER.

OBSTETRICS FOR MIDWIVES

A Textbook for Midwives. By Wilfred Shaw, M.D., F.R.C.S., F.R.C.O.G. (Pp. 689; 223 illustrations. 12s. 6d.) London: J. and A. Churchill, Ltd. 1948.

Wilfred Shaw has already set a high standard as a writer of textbooks and his reputation will certainly be enhanced by this new book for midwives. It is clear that in preparing the work he has had in mind what he himself calls "the serious student," and particularly the nurse who is preparing herself for the Teachers' Diploma. Realizing, however, that the nurse may be deficient in her knowledge of basic sciences, he has included sections on certain aspects of physiology, chemistry, and physics; he discusses, for example, osmotic pressure, dialysis, crystalloids and colloids, adsorption, and the mechanisms of cell division. He has thoughtfully added a glossary of the more difficult technical terms used throughout the book.

In the main subject-matter there is little to criticize and much to praise. The teaching is similar to that presented in the author's well-known textbook on obstetrics for medical students, though he has necessarily modified certain aspects to make it suitable from the point of view of the midwife. As with Shaw's other textbooks, this one contains numerous and carefully chosen illustrations, many of which are reproductions or redrawings of the illustrations in standard German textbooks.

The concluding chapters take the form of short sections on cancer of the uterus and breast; definitions and statistics; a short history of the development of midwifery; the Central Midwives' Board and the local supervising authority; the midwife-doctor relationship and the future of midwifery.

This book can be thoroughly recommended to the more advanced midwife. The style of writing is simple and clear and a full explanation is given—when explanation is possible,—of the whys and wherefores of obstetric practice.

J. CHASSAR MOIR.

Zinc Ions in Ear, Nose, and Throat Work, by A. R. Friel, M.D., F.R.C.S.I. (pp. 60; 41 illustrations; 5s. 6d.; Bristol: John Wright and Sons, 1948), is a small book that sets out in detail the methods of performing zinc ionization as a curative treatment of chronic middle-ear suppuration, hay fever, asthma, and vasomotor rhinitis. In a preliminary chapter the author recites the history of the origin of this treatment, instituted by Dr. Ledue, and with the help of many clear illustrations explains the electrical principles involved. Zinc electrolysis is also advocated for destruction of tissues, including bone and nasal polypi. The value of the thesis would be enhanced if it included results of the therapy. The clear illustrations will be of great help to those who intend to use this treatment.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

On the Contributions of Hugh Owen Thomas, Sir Robert Jones, and John Ridlon to Modern Orthopedic Surgery. By H. W. Orr, M.D. (Pp. 253. 25s.) Oxford: Blackwell Scientific Publications. 1949.

Shaw on Vivisection. Edited by G. H. Bowker. (Pp. 65. 5s.) London: George Allen and Unwin. 1949.

Dentistry in Public Health. Edited by W. J. Pelton, B.S., D.D.S., M.S.P.H., and J. M. Wisan, D.D.S., M.S.P.H. (Pp. 363. 27s. 6d.) London: W. B. Saunders. 1949.

Population Trends and Policies. By W. D. Borrie, M.A. (Pp. 263. 21s.) London: George G. Harrap. 1948.

No Place to Hide. By D. Bradley. (Pp. 191. 7s. 6d.) London: Hodder and Stoughton. 1949.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JUNE 25 1949

A POPULATION POLICY

There are few more complex problems than the future of the population of this country, and it is hardly a matter for surprise that in taking stock of it the Royal Commission on Population has spent five years and rather more than £200,000—a very great part of which sum was the cost of special statistical surveys. The task of the Commission was "to examine the facts relating to the present population trends in Great Britain, to investigate the causes of these trends and to consider their probable consequences; to consider what measures, if any, should be taken in the national interest to influence the future trend of population; and to make recommendations." In its work it has been assisted by three scientific committees: statistics, presided over by Sir Alexander Carr-Saunders; economics, presided over by Sir Hubert Henderson (the Chairman of the Commission after the resignation of Lord Simon); and biological and medical, presided over by Professor A. W. M. Ellis. The many reports and papers that these committees have submitted to the Commission will themselves soon be published in a series of volumes, including the results of the sample family census taken in 1946. The Report of the Commission itself,¹ published this week, surveys these detailed studies from a broader standpoint, summarizing them in simple form or quoting the results it needs in the development of its arguments. It has thus produced a readable as well as a highly important document.

Historically we know little of the population of Great Britain before the eighteenth century, though there can be little doubt that it grew very slowly. The seven million estimated, with reasonable reliability, to be the total number in 1700, had increased to 10½ million at the first census in 1801 and to 37 million a hundred years later (with close upon 50 million to-day). Such a rapid rate of growth had inevitably to come to an end, either through the Malthusian checks of famine and disease or by some other means. Already one of the most densely populated countries of the world, with some 600 persons to the square mile, we should have been faced with disaster by a continuation on any such scale. As everyone knows, the correcting factor came with the fall in fertility that began about 1870. Taking the two ends of the time scale, the special questions included at the census of 1911 show that married women born in 1840-60 produced, on the average, a family of five to six children; for women married in 1925-9 the family census of 1946 gives only a fraction over two children for their completed families. Of the Victorian group 20% had families of two or less, 33% had families of eight or more; the corresponding figures for women married in 1925 are 67% with no, one, or two children, 2.3% with eight or more. That phenomenon, coupled with greatly reduced rates of mortality at nearly

every age, is the salient fact in the modern history of our population.

It has been argued by some that unnatural and unhealthy ways of living have reduced our reproductive capacity, though the improvement in standards of health to-day might well be expected to have quite the reverse effect. However that may be, the Commission accepts the views of its medical committee that no physiological or biological factor would prevent married couples having larger families to-day if they wished. They do not wish; or, in other words, deliberate birth control is the significant feature, and from this adjustment to modern life it is neither likely nor desirable that there should be any return. There has been, however, during the course of the Commission's work, a particularly interesting check to the fall in the number of births, and, indeed, in the later years of the war and in the post-war years a very large increase. Some decline in these larger numbers has, however, been apparent recently, and it is likely that the increase is a temporary feature due to younger marriage and also to the fact that the average size of family has, at least for the time being, ceased to decline. For the past twenty years it has been comparatively stable at 2.2 children, and there is some evidence that the very small family is no longer as fashionable as it was in the early 1920's. This present number, however, is calculated to be about 6% below what is needed for the replacement of the population (a much less pessimistic figure than that based in pre-war years upon net reproduction rates).

What then of the future? We now enter to some extent upon the realm of uncertainty; but it is well to realize that it is only to some extent, that apart from immigration the stage is in some respects already set. Thus inexorably from the present age distribution of the population it follows that, immigration apart, the number of young adults (15-39) must fall over the next fifteen years: in 1947, of every 100 persons 28 were aged 0-19 and 30 aged 20-39; and clearly 28 cannot fully replace 30. At the same time the number of old people (over 65) must grow steadily for the next thirty years even if no appreciable fall in mortality takes place, which with the present advances in medical knowledge is clearly most unlikely. In 1891, 7% of the population were of ages 60 and above; in 1947 it was 15%. The final group upon which we can speak with some certainty is the population of working age, which will remain at about its present absolute size for at least the next thirty years though it will come to form a smaller proportion of the total. If we turn to the unknown, there is a possibility, as already suggested, that the one-child or two-children families may become less common. On the other hand, in completed families of to-day one in five have four or more children, so there is room for further shrinkage here. If, however, average family size remains as in the period of stability in the early 1930's, the population will reach a maximum in about 1977 and thereafter begin a slow decline. If, on the other hand, there is a further reduction in family size—and not necessarily a very large one—then the decline of annual births will become rapid, and well before the end of the present century the numbers of children and young adults will be falling rapidly.

¹ Report of Royal Commission on Population, H.M.S.O. Cmd. 7695 p. 259.

but the reason why it could not happen illuminates the difference between the brain and a machine. Jefferson points out the inadequacy of words to express many of our experiences, especially our feelings. But these are the very stuff of which poetry is made. The poet, unlike the abstract thinker, uses words not for their definitive but for their associative power, to create in his hearer by means of images, ideas, and even rhythms the feelings he has himself experienced. He succeeds in so far as he thus expresses the inexpressible. But what evidence is there that feelings can be identified, not merely correlated, with electrical rhythms which could be induced in a machine?

There is an undeniable danger in the facile acceptance of materialism, for the materialist finds values and ethics an insoluble problem. If the mind is ultimately mechanical, what is the source of its standards of right and wrong? These can be only the result of individual and social conditioning and can have no more than personal validity. Individuals differ, States conflict with one another, and it is useless to appeal to the evolutionary process. That knows neither higher nor lower: it has produced the tapeworm as well as man, and issued impartially to each its approval-certificate of survival. If man prefers complexity and richness of experience, this is just human prejudice: the tapeworm is all for the simple life and adaptation to environment. It is illuminating to see how a machine may be expected to deal with an ethical problem. An electrical calculating machine can perform in a few hours a calculation which would take a mathematician many months. How, then, are the machine's results to be checked? Wiener, to whose book *Cybernetics* Jefferson alludes, explains that this is done by setting three machines the same problem and, if they do not all agree on the answer, accepting the verdict of the majority. Inevitably in the world of machines ethics is decided by the majority. This generation, at least, knows where that doctrine leads—to tyranny, the concentration camp, the gas chamber, and the cremation oven.

Whitehead, in *Science and the Modern World*, has pointed out that science arose in opposition to current mediaeval ideas, which were rationalistic. Science, with its emphasis on brute fact, "has remained predominantly an anti-rationalistic movement based upon a naive faith." The danger of rationalism lies in its systematizing tendency, which tidies up the loose ends of thought. But the main facts of a science may be equally consistent with several theories: it is often the details that are decisive. It was a few minute discrepancies between the Newtonian theory and certain astronomical observations that led to its supersession by the theory of relativity. Theorizing about the body-mind relationship is premature. Many years of work lie ahead before the decisive details will be uncovered. This work needs to be done in the spirit of science and not of rationalism. When we think about the mind it is with the mind that we do this, and the mind must surely be greater than its own ideas about itself. If we fail to recognize this, we may suffer the fate of the inhabitants of Butler's *Erewhon* and be enslaved by machines, not, however, because of their intrinsic force but because, like Narcissus, we have fallen into the power of our own reflection.

PROCAINE PENICILLIN

The use of "depot" or "repository" preparations is by far the most satisfactory of the many methods devised for prolonging the action of penicillin with the object of reducing the discomfort of multiple injections. The disadvantages of the oil and wax preparation described by Romansky and Rittman¹ in 1944 have now been overcome by the discovery by Salivar, Hedger, and Brown² of an insoluble salt of procaine and penicillin which is slowly absorbed from the site of injection. Recent papers appearing in this country confirm the favourable results obtained by workers in the U.S.A. Trials in adults of procaine penicillin suspended in arachis oil (300,000 units per millilitre), reported by Jones and Shooter³ and Young, Andrews and Montgomery,⁴ have shown that in over half the cases therapeutic blood-penicillin levels were present 24 hours after a single injection of 300,000 units. When the oily suspension of procaine penicillin is combined with aluminium stearate, absorption is further prolonged, and 24 hours after a dose of 300,000 units the blood penicillin is still at a therapeutic level.⁴

The value of these preparations in paediatric practice is due not only to their prolonged action but also to the complete absence of pain on injection. Experience of their use at the Sheffield Children's Hospital has confirmed the results obtained in adults. Using the oily suspension of procaine penicillin in doses graded according to age, Emery, Stewart, and Stone, whose report was published in the *Journal* of May 14 (p. 845), found that blood levels were too variable for reliance to be placed on once-daily injections—only 29 out of 50 cases having a blood-penicillin level of 0.03 units per ml. or over after 24 hours. Wilson, Farquhar, and Lewis⁵ obtained similar results in older children, but found that blood levels were higher in infants up to 15 days old.

Elsewhere in this issue Drs. J. L. Emery and L. M. Rose, Miss S. M. Stewart, and Professor E. J. Wayne report on the use in children of procaine penicillin in oil combined with aluminium stearate. They used a preparation in which over 95% of the particles were below 5 μ in diameter. Sixty-six children were given intramuscular injections in doses graded according to age: those under 1 year were given either 75,000 or 150,000 units, children aged 1 to 4 received 150,000 units, while older children were given the full adult dose of 300,000 units. All except one had blood-penicillin levels of 0.06 units per ml. or over at 24 and 48 hours. In eleven children daily injections maintained a high continuous level in the blood. Undesirable reactions were absent. These authors conclude that procaine penicillin in oil with aluminium stearate is a suitable preparation for once-daily injection. Owing to slow absorption it might be expected that the blood penicillin would not rise quickly, but in many cases surprisingly high initial levels have been recorded.⁴ Young, Andrews, and Montgomery,⁴ for example, state that four hours after an injection of 300,000 units blood levels as high as 4 units per ml. may be found. In order to test the hypothesis that renal excretion of procaine penicillin was slower than that of sodium penicillin, Barnett and his co-workers⁶ measured the renal clearance rate in infants and children of sodium and procaine penicillin, but failed to demonstrate any significant difference. It thus appears that the action of these substances is due only to delayed absorption. These preliminary reports indicate that the addition of procaine penicillin to the preparations available is another step forward in penicillin therapy, and further reports of its use, especially in those cases needing prolonged treatment, will be awaited with interest.

PHAECHROMOCYTOMA

Adrenaline-producing tumours of the adrenal medulla, the phaeochromocytomata, are a rare but often notable cause of hypertension. The literature contains accounts of nearly 200 patients with such tumours, of whom 64 have been operated on with 12 deaths. Mr. T. M. Reid and Dr. R. Salm report a further case in this issue of the *Journal*. The commonly described symptoms are those referable to the sudden outpouring of adrenaline into the blood stream in response to postural changes, exercise, pressure on the abdomen, straining at stool, or emotional disturbances such as anger or fear. This release of adrenaline causes a rapid rise in blood pressure to very high levels, usually accompanied by severe headache. Other symptoms not unlike those associated with functional nervous disorders also commonly occur, such as anxiety, weakness, dizziness, sweating, nausea, vomiting, and dilatation of the pupils. These attacks are typically of short duration, and when clear cut are sufficiently unusual to lead frequently to the right diagnosis. But if attacks are long continued they may result in a more persistent hypertension, with renal damage, cardio-vascular disturbance, papilloedema, and other retinal changes, which may make the diagnosis from malignant hypertension difficult—especially in the small proportion of cases in which a history suggesting paroxysmal hypertension may be absent.

Recently several functional tests have been introduced which aid considerably the recognition of hypertension due to over-production of adrenaline from such a tumour. Roth and Kvale¹ have shown that small doses of histamine (0.05 mg.) injected intravenously will stimulate a paroxysm of hypertension in cases of phaeochromocytoma, with a systolic pressure even as high as 300 mm. Hg. But less extreme rises may occur which can be difficult to interpret. Since histamine-sensitive individuals may react with a moderate rise. Believing the histamine test unreliable, Guarneri and Evans² suggested the use of "mecholy" (acetyl- β -methylcholine chloride), which they found in one case of phaeochromocytoma caused a short, sharp rise in blood pressure—the normal response being a slight fall. There has as yet been insufficient experience with this test. Both tests have the definite disadvantage that the results of an unduly sharp hypertensive response may be serious. For this reason the use of the new anti-adrenaline compounds will probably be more satisfactory. Goldenberg, Snyder, and Aranow³ have demonstrated that in cases of phaeochromocytoma intravenous benzodioxane in doses of 0.25 mg. per kg. of body weight causes a drop in blood pressure lasting about 15 minutes. In one of their cases a tumour was removed, and subsequently a fall in blood pressure was still found after injection of benzodioxane. This was interpreted as evidence of the presence of further adrenaline-producing tissue, and at a second operation another phaeochromocytoma was removed.

More recently Spear and Griswold⁴ have used a different adrenolytic compound, dibenamine, for the same purpose. Given by slow intravenous injection in doses of 7 mg. per kg. body weight, this also causes a pronounced fall in blood pressure to normal levels. Its action is much more prolonged than that of benzodioxane, and for 24 hours after injection it will prevent further spontaneous attacks and will also prevent the rise of blood pressure ordinarily provoked by histamine. Because of this more prolonged action dibenamine is likely to be of great value not only in diagnosis but also in the pre-operative preparation of patients, for the main causes of the high operative mortality

are the rapid outpouring of adrenaline during manipulation of the tumour and the subsequent shock resulting from sudden diminution of the supply of adrenaline after its removal.

BENIGN PROSTATIC HYPERTROPHY

Study of the aetiology of benign prostatic hypertrophy has been hampered by the fact that many of its characteristics are peculiar to man; it occurs in only one other animal—the dog—and so far it has been impossible to produce hypertrophy experimentally. The common and reasonable view is that the hypertrophy results from some endocrine disturbance occurring in the fourth or fifth decade of life, which is perhaps comparable to the climacteric. In a review of the subject Huggins¹ concludes that in the dog the process of enlargement—a cystic hyperplasia—is governed by two factors—time and testicular secretion. In man the lesion is composed of multiple spheroidal nodules made up of epithelium, muscle, and fibroblasts. Histologically these nodules are benign tumours, an observation which is supported by their type of respiration.² In the mouse, guinea-pig, and monkey the prostate has two separately functioning parts.³ From evidence based on embryological research⁴ and the response of the prostate to oestrogen administration Huggins considers that the human prostate has two different functional areas. The spheroidal nodules are seen only in the medullary region. Since the prostate does not become enlarged in early life, presumably the stimulus to enlargement acts over a long period. The lesion does not occur in castrates, and it is therefore reasonable to suppose that the stimulus is testicular in origin. In dogs with an established hypertrophy castration causes a shrinkage but not complete disappearance of the lesion. Huggins studied the effects of orchidectomy in men suffering from benign prostatic hypertrophy and noted relief of the obstructive symptoms, with diminution in the size of the gland but not disappearance of the spheroidal nodules. He also treated a series of cases with oestrogen in doses sufficient to cause breast growth. The changes produced were those of mild injury to the epithelial cells of the acini in the medullary portion of the gland: the cortical area was unaffected. These observations serve to confirm the importance of androgen in the aetiology of benign prostatic hypertrophy.

AN "EYE BANK" ESTABLISHED

That corneal-graft surgery now has many applications in the treatment of blindness due to injury or disease of the cornea was the opinion of ophthalmologists from many countries who were present at the recent Congress of the Ophthalmological Society of the United Kingdom. It was indicated that the fashion of the graft is changing and that the partial graft is returning to favour. This type of graft does not penetrate the entire thickness of the cornea, and there is, therefore, no risk of iris adhesion to the corneal section, with consequent formation of opacities in the graft. Many successful grafts have been performed in this country, but surgeons have had to contend with considerable difficulties. Living grafts are scarce and, like hospital beds, may not be available just when they are required. The infrequency of the operations makes it difficult to arrange for postgraduate tuition at short notice.

⁵ Lowsley, O. S., *Amer. J. Anat.*, 1912, 13, 299.

Donor grafts can now be preserved in oil or vapour in an "eye bank," and are suitable for use up to three days after removal from the living or cadaver eye. Some authorities claim better results with preserved grafts. As the scope of the operation widens, the demand for instruction in technique from home and overseas increases, and an adequate supply of donor grafts for treatment and post-graduate instruction has become essential. Not long ago a letter was published in the *Journal* (Dec. 4, 1948, p. 999) from an Australian doctor who deplored the absence of an eye bank in this country. Now, to meet the need, the South-east Metropolitan Regional Hospital Board has established a corneo-plastic unit and eye bank in conjunction with the plastic centre at East Grinstead. With the co-operation of ophthalmic surgeons in the region, and with assistance from other sources, a supply of donor grafts will be preserved. This will provide increased opportunities for treatment and improved facilities for instruction and study.

The resources of this unit, however, will not be entirely limited to corneal-graft surgery; they will also be available for the special cases which are the joint problem of ophthalmologists and plastic surgeons. Such cases include severe injuries of the lids and orbit, resulting in complicated lacrimal obstructions or paralyses of extra-ocular muscles. The surgical treatment of the various forms of ptosis, congenital abnormalities of the lids, and the lacrimal apparatus, new forms of enucleation with implantation, and the applications of modern prostheses are all examples of subjects for clinical research. Thus, a combined team of ophthalmologists and plastic surgeons, aided by the facilities of a modern plastic unit, will bring special interest and experience to bear on these problems. The South-east Metropolitan Regional Hospital Board is to be congratulated for sponsoring the formation of such a unit, which is a welcome addition to the resources of British ophthalmologists and an asset in the treatment of blindness in this country.

PAIN IN PHANTOM LIMBS

A phantom limb is a natural consequence of amputation and is experienced by the majority of patients. A painful phantom, however, is a rarer condition. In Henderson and Smyth's¹ series of 300 patients of military age only 4% had painful phantoms, though others have reported a higher incidence than this, possibly on account of the age and other special features of patients whom they were studying. Henderson and Smyth concluded from their detailed study of the symptoms of phantom limbs that various epiphenomena may occur; in some patients there was a "neuroma sensation," which resulted from the mechanical stimulation of neuroma in the stump and consisted of instantaneous sensation of pins and needles referred to the peripheral distribution of the divided nerves. In a minority of cases only there were complaints of pain, distorted attitudes of the phantom, and involuntary spasmodic movements, all of which the authors considered were of psychological origin. This view of the cause of pain in phantom limbs is not universally held, and the pain is often considered to be of peripheral origin.

Many methods of relieving the pain have been tried, including local excisions of the neuroma, sympathectomy, posterior rhizotomy, chordotomy, and even excision of areas of the parietal cortex.² In a preliminary report which was published in the *Journal* of June 1949,³ Dr. W.

Ritchie Russell suggested a much simpler procedure than these operations; it has been successful in seven cases, several of them of long standing. The method was introduced for three reasons: first, the observation that in the normal limb nerve endings in the skin are rendered insensitive by occupations which entail repeated minor traumata or prolonged firm pressure on the skin; secondly, that conduction in a mixed nerve is easily interrupted by repeated pressure without the production of any spontaneous pain; and, thirdly, on the assumption that regenerating nerve fibres in an amputation stump are likely to be no less vulnerable to minor trauma or pressure than normal nerves and nerve endings. The practical application of this reasoning was to percuss the neuromata into a state of "chronic concussion." As this can be a somewhat painful process at the onset, a local anaesthetic may be injected into the stump or a sphygmomanometer cuff may be applied to the stump and inflated to over 200 mm. Hg, which renders the tender scars and neuromata less sensitive after two to three minutes. Percussion is carried out by gentle hammering with a small wooden mallet or mechanical vibrator and continued with increasing vigour for about ten minutes. It is advisable to use a wooden applicator to transmit the blows of the mallet to the neuromata. At first treatment must be repeated at least twice a day, but in some cases once daily was sufficient; as Dr. Ritchie Russell puts it, "The patient soon learns to knock away his phantom pain whenever it becomes troublesome."

This is a refreshingly simple method conceived on sound physiological principles if the major hypothesis is accepted that pain in phantom limbs is of peripheral origin. If the method should prove successful in a large number of cases it would serve as additional proof for this hypothesis, though it would still be difficult to explain the failure in some cases of division of sensory nerves and posterior roots to relieve the painful phantom.

VISCOUNT ADDISON

Viscount Addison attained his 80th birthday on June 19, and will have the good wishes of the profession in continuing a career that has been fruitful in both medicine and politics. He was the first whole-time lecturer in anatomy at St. Bartholomew's Hospital, and later held the chair in that subject at University College, Sheffield, subsequently serving as examiner for the Universities of Cambridge and London. In 1910 he was elected to Parliament as the Labour member for the Hoxton division, and soon after the outbreak of the first world war he was transferred to the Ministry of Munitions, where he served under Mr. Lloyd George, and in 1916 succeeded him as Minister. In 1919 Dr. Addison, as he then was, became the first Minister of Health when the new Ministry was established. The only other medical man to have held that office is Mr. Walter Elliot. In 1929 he was returned as Labour member for Swindon, and was Minister of Agriculture in 1930-1. In 1937 he was raised to the peerage—the fifth medical man to be made a peer—and when the National Government was dissolved in 1945 he received a viscounty. He has been Leader of the Labour Party in the House of Lords since 1940.

Dr. J. H. Sheldon, F.R.C.P., will deliver the F. E. Williams Lecture before the Royal College of Physicians of London, Pall Mall East, S.W., on Tuesday, July 12, at 5 p.m. His subject is "The Role of the Aged in Modern Society."

A NOTE ON ELECTRIC AUTOMATIC COMPUTING MACHINES

BY

M. H. A. NEWMAN, F.R.S.
Manchester University

Although these devices are sometimes called "electronic" or "mechanical brains," they are designed for one specific purpose, the rapid performance of large pieces of numerical computation. To enable them to do this they are provided with a storage which holds numbers and instructions in a form suitable for triggering off various kinds of activities in the machine. The usual method is first to code the number or instruction as a row of 0's and 1's (by using binary instead of decimal notation in the case of numbers). A large number of stations, say a quarter of a million, are provided in the machine, each of which can be in one or other of two states, called "0" and "1," and a coded number or instruction is set up accordingly on a row of perhaps 40 of these stations. The earlier electronic machines, such as ENIAC, used a pair of radio valves for each station, but this led to a large expenditure of power in running the machine, and other methods have since been invented. The Manchester machine, referred to by Professor Jefferson in his Lister Oration, uses Professor Williams's storage, in which each station is a charged spot on the coating of a cathode-ray tube, large or small for 1 or 0. One tube holds about 2,500 spots. It is likely that all such machines will have a large magnetic storage as a secondary resource. This form of storage is very stable, and requires no power supply for its maintenance once the material is written in, but it is less accessible than electrical storage.

The machine operates by carrying out the instructions one after another, each instruction having some such form as "multiply this row by that row" or "copy this row into that." If it were necessary to put an instruction into the machine for each of the many millions of operations involved in a big computation it would obviously take as long to write in the instructions as to do the computations by hand. The feature that enables the machine, like a properly trained human computer, to work from a short table of instructions is its power of choosing which instruction to perform next, on the basis of the results of work already done, and hence to use the same instruction over and over again.

The speed of the machine is of the order of 1 millisecon. per elementary operation, a typical elementary operation being the addition or multiplication together of two numbers of 40 digits (in the scale of 2, =12 in the scale of 10). This is perhaps 10,000 times the speed of a human computer working with a desk calculating machine, without allowing for resting time.

This takes no account of the time required to get the problem coded for the machine, but it appears that this is a less formidable problem than was at first supposed, and may become very rapid when standard small routines have been worked out which can be tied together to make large ones. This is a matter on which a rapid increase of information may be hoped for now that machines are actually beginning to come into operation.

The variety of computing problems that can be handled by machines of this kind, by setting up a suitable table of instructions on them, is very great, including the approximate solution of partial differential equations, problems involving large integers (e.g., searching for primes), and questions in more abstract parts of mathematics. Indeed, convincing arguments have been given by Turing for the view that these are "universal" computing machines, in the sense that any well-defined piece of computation whatever could be done on them from a single table of instructions, given sufficient time and a large enough storage for numbers and instructions. In this they differ from such a machine as the ENIAC, which, though very flexible, is limited to a certain (large) repertory of possible assignments.

The expression "piece of computation" has a wider connotation than might at first be supposed, since many pieces of work which have at first sight nothing to do with arithmetic can be "coded" so as to consist of arithmetic operations. For example, the playing of a legally correct game of bridge, poker, or chess can certainly be so coded, and in this sense the machine could play these games. (Whether it could be made to play a good game is a different question.) It is no doubt the possibility of such non-mathematical applications that has led to these machines being brought into discussions on the thinking potentialities of machines, and to the suggestion that the human brain is itself a network of units of this general type. There is evidently a danger here that extravagant powers will be credited to these devices, and conclusions drawn too rapidly about biological analogues; but some caution is also necessary in coming to final conclusions in the opposite direction, on the basis of our knowledge of the behaviour of a small pilot model of this very new kind of machine, designed for a sharply limited purpose, which has been in rather halting action for a few months. The first question that will have to be asked is not "Can all kinds of thought, logical, poetical, reflective, be imitated by machines?" but "Can anything that can be called 'thought' be so imitated and, if so, how much?" The most promising line here will be to work within mathematics itself, to see how far the work of instruction-table making can be gradually transferred from the mathematician to the machine. The work of modern mathematical logicians gives us a good idea where the barrier is likely to be found, but this is too deep a question to pursue further in this note.

The "Mechanical Brain." The section on the left contains the control circuit, in the middle rack of which is a cathode-ray tube screen with (below) the control desk. The racks on the right-centre of the picture provide the "memory" section. Nearer the camera are racks for calculating circuits. The machine is "fed" at the control desk and the answer is read on the cathode-ray tube screen. For this illustration we are indebted to the Electrical Engineering Laboratories, Manchester University.

CARE OF ELDERLY PATIENTS

LONDON REGIONAL CONFERENCE

The need for co-operative effort in dealing with infirmity in old age was discussed at a conference in London on June 1 attended by over 200 representatives of local authorities in the Metropolitan area, the Ministry of Health, three regional hospital boards, and fourteen grouped hospital management committees, the King Edward's Hospital Fund, and certain voluntary organizations. The convening body was the Regional Advisory Committee for Old People's Welfare, under the auspices of the London Council of Social Service. The conference was presided over by Mr. FRED MESSER, M.P., and Miss D. RAMSEY, respectively chairman and secretary of the National Old People's Welfare Committee.

Limitations and Achievements of a Geriatric Unit

Dr. T. H. HOWELL, who is in charge of the geriatric unit at St. John's Hospital, Battersea, described the growth of geriatric clinics, and referred in particular to the clinic associated with University College Hospital. Another centre was in Liverpool, where a gloomy "chronic" hospital had been changed into a centre of cheerfulness and "re-ablement." His own unit at Battersea arose out of a determination to treat by every possible means chronic arthritic conditions in the old. As a result a number of people who formerly were regarded as hopeless wrecks were relieved of pain and eventually made fit to leave hospital. The trouble was that in solving a medical problem a new medico-social problem had been disclosed, for it often happened that there was no home to which these old men and women could return. In one London hospital 17% of these patients were up and about, needing little or no treatment, but they could not be discharged because there was nowhere for them to go.

At first he had been depressed by the growing waiting-list for admission to beds, but this was met in part by the setting up of an out-patient department combined with the follow-up of patients who had been discharged. This out-patient department had become so popular that a special session had to be set apart for people coming from a distance. The out-patients went through their exercises and their occupational therapy, and received their medicine, and a fair number of them who had been waiting for beds improved to such an extent that their names were taken off the waiting-list.

Some patients suffering from bronchitis were taken into hospital for a short time to enable them to get over the worst of the winter season, and then they resumed their out-patient attendances. In this and other ways a turnover was obtained which had been undreamt-of previously in a "chronic" hospital. There was nothing more heartbreaking for the general practitioner than the problem of the old person who needed more attention than the doctor could possibly secure for him. The geriatric unit had relieved that situation; it had also wiped out the motto, "Keep them in bed and keep them quiet," substituting, "Get them up and keep them interested." That was not enough, and the motto for the future must be, "Catch them quick and treat them early." The only reason why there were not more of these geriatric units was because there were not enough doctors and nurses to run them.

One great necessity, said Dr. Howell, was a half-way house for the accommodation of old people who were not well enough for an independent life in their own homes and not ill enough for hospital. Formerly many such patients would have had to enter public assistance institutions, of which, reasonably, they had a great dread. It was true that some public assistance institutions were like barracks, but others were comparable with old people's homes; he had seen some which he would not mind living in himself. It had been possible in some cases to humanize these institutions, and he saw no reason why this should not be done in all of them.

Long-stay Annexes and Home Care

Dr. E. B. BROOKE, medical superintendent, St. Helier Hospital, Carshalton, reminded the conference of the ageing of the population. One person in seven was over 60, and in twenty years' time it would be one person in five. While he still believed

whole-heartedly in the scheme set out by the British Medical Association for a co-ordinated service for old people, he was now pessimistic about the realization of the ideal in its entirety in the measurable future. The scheme proposed that after patients had received every possible "re-ablement," those who still required care and maintenance but not active medical treatment should be moved into long-stay annexes, which would be homely and comfortable for them, and would release hospital beds for other patients. These long-stay annexes, upon which the scheme hinged, he viewed with some misgiving. He doubted whether it would be possible to start enough of them, and he thought some workable alternative should be proposed.

The alternative which he suggested was home care backed by every support the hospital could afford short of admission to its beds. The problem in a nutshell was, "Too many patients in search of too few staffed hospital beds." The obvious solution appeared to be more staffed beds, or, failing that, the use of the available beds to the best economic advantage by providing a turnover of patients and long-stay annexes for cases that might otherwise silt up this steady flow. He mentioned the case of eight old men who had all been in hospital for just over three years until recently, when they were transferred to rather more homely accommodation. Their eight beds in that period could have been used by between 400 and 500 surgical cases. Out-patient facilities, with transport, could keep many patients out of hospital.

At St. Helier's, when the problem was first tackled, there were empty pavilion wards in a near-by hospital which might have been used as a long-stay annex but it was not possible to staff them. He then realized that the only solution was by out-patient and home care so far as this could be provided. It must be remembered that the elderly patient, the geriatric patient, and the chronic patient were not synonymous terms. Old people, like others, included "acutes" and "chronics." In the later decades obviously a larger number were not able to return to full activity. There was an understandable apprehension lest the admission of old people to hospital should steadily worsen an already bad situation. The majority must be left at home, and there must be reproduced for them so far as possible the facilities available for the more fortunate few who had gained admission.

Hospital Priorities

Meanwhile, said Dr. Brooke, efforts must be concentrated on the individual cases which demanded admission to hospital most urgently on the grounds of medical and social necessity. The following were admitted to the short waiting-list for hospital beds:

(a) Those with a reasonable chance of "re-ablement" which would not be available to them other than by in-patient treatment;

(b) Elderly patients who needed the added comfort of hospital in the terminal stages of their illness when they would otherwise die under distressing conditions at home;

(c) Old people whose admission was necessary for the benefit of the younger generation (a category which required careful scrutiny).

Other priorities, though not necessarily on such a short-term basis, were: (1) patients who were entirely alone in the house at night; (2) patients with double incontinence; and (3) old people who were restless and possibly confused in their senility.

In hospital there were facilities for diagnosis and treatment, nursing care, medico-social advice and information, a bed with clean linen, and warmth and food. The assessment of elderly patients recommended for admission should be undertaken, as in the case of tuberculous patients, at a domiciliary consultation or by transporting the patient to the out-patient department. The family doctor would find that for the patient at home many amenities were available through the resources of statutory and voluntary bodies.

The home help service had made immense strides recently. It had developed certain specialized types—the night home help, the male help, often useful in attending certain male cases, even the help who was colloquially called, the "popper-in." A domiciliary laundry service would be of great value. Perhaps the medical officer of health could obtain authority to provide laundry facilities for certain specified types of patients. He also looked forward to a combination of the school meals service and an old people's meals service. He agreed with

Dr. Howell that the great need was for a half-way house for patients neither fully ambulant nor bedfast.

During the past eight months at St. Helier's they had dealt with 203 elderly patients (two women to every man) either by direct admission or by home care or some alternative arrangement. The main problem had been solved for all but 33 of these patients. These 33 were on the current list, but they were not merely a list, they were a "phantom ward." Officers of the hospital made a round among them, and the patients' relatives knew that they could communicate with the hospital at any time by telephone and that any call would have an immediate response.

Home Helps

In the general discussion that followed it was suggested that home helps or home nursing services in one form or another were saving the hospitals the care of many chronic cases and enabling them to direct their activities more economically, therefore a certain amount of money which at present went to the hospitals might well be transferred to these agencies. Mr. R. A. STAMP, chairman of the Health and Hospital Services Committee of the L.C.C., said that the home help service was comparatively new. Some borough councils were active in this respect, others were not. Home helps were doing a lot of the work that the National Health Service Act intended that the hospitals should do. If the four regional hospital boards which covered the metropolis, as well as the voluntary bodies with which his council had contractual arrangements, would be prepared to work out a scheme for dealing with the position, with the Minister of Health brought into the discussions, it might be of very great advantage. It seemed necessary to have some reallocation of financial assistance as well as a redefinition of responsibility.

Mrs. E. WIGLEY, of the British Red Cross Society, described the home visiting work done by that organization. Mrs. A. V. HILL spoke of the great handicap under which those responsible for homes for old people laboured, in that while they started with the more or less able-bodied the inmates became progressively more infirm and feeble and unable to perform slight services for others or even to look after themselves.

Mr. FRED MESSER, M.P., in closing the conference, said that there seemed to be a case for closer co-operation all round. It was remarkable that hostels were available for discharged prisoners but not in any number for old people, an indication that in society fear was a more powerful motive than duty or affection.

INTERNATIONAL HOSPITAL FEDERATION

FIRST POST-WAR CONGRESS

The International Hospital Federation held its first post-war Congress in Amsterdam and Groningen from May 30 to June 4. It was attended by 353 members and their friends from Australia, Belgium, Denmark, Egypt, France, Italy, Norway, Portugal, Sweden, Switzerland, and the United States.

Dr. René Sand, of Belgium, the president, who opened the Congress, was supported by Jonkheer Röell, representing H.M. the Queen of Holland, Patroness of the Congress, Mr. A. M. Joekes, Minister of Social Service, Mr. d'Ailly, Burgomaster of Amsterdam, Dr. Van den Berg, Deputy-Director of WHO, and members of the Dutch Hospital Association.

"The Vocation, Aim, and Task of Hospitals" was discussed by three speakers—Dr. E. Hoelen, medical director, Miss M. Stenvers, matron, and Mr. A. M. Spiering, chaplain—selected by the Dutch Hospital Association. There followed a paper on "The Influence of Economic and Social Changes on Hospital Administration" by Professor F. Pulcher, of Genoa. Then came a paper on "Modern Trends in Nursing Training and Nursing Practice" by Mrs. B. A. Bennett, chairman of the Nursing Service Committee of the International Council of Nurses. The discussion on this subject was opened by Dame Katherine Watt, chief nursing adviser of the Ministry of Health.

The third day was devoted to the discussion of two papers: "The Training of Hospital Administrators," by Mr. George Bugbee, executive secretary of the American Hospital Association, and "Personnel Management in Relation to Hospital

Service," by Mr. H. N. Appelbe, personnel manager of St. Thomas's Hospital.

The second stage of the Congress, at Groningen, began with an outstanding address on "Modern Tendencies in Hospital Design, Construction, and Equipment" by Mr. Hugo van Huyck, technical counsellor of the Antwerp Public Assistance Board. Then Dr. Van der Leen, of Holland, gave a paper on "Hospital Budgets and Budgetary Control," and Mr. S. Clayton Fryers opened the discussion on this theme.

The final paper was by Dr. Charles T. Maitland, of the Ministry of Health, who spoke on "The Regional Planning of Hospital and Health Facilities." Here a full and interesting discussion was opened by Sir Ernest Rock Carling and Dr. Vane Hoge, of the United States Public Health Service.

Plans for the Future

The success of the Congress was due in no small measure to the skill with which Dr. René Sand guided its deliberations. The numbers present and the high standard of most of the formal addresses showed how generally welcome was the idea of reviving in this form the pre-war meetings which the former International Hospital Association arranged biannually. They began at Atlantic City in 1929 and continued at Vienna, Knockesurmer, Rome, and Paris in 1937. The Toronto conference of 1939 had to be abandoned, but the American Hospital Association has invited the Federation to hold its next congress in Atlantic City in 1951. For next year a study tour in Scandinavia is proposed. Although the generosity of the Americans in inviting the next congress to the birthplace of the old association was highly appreciated, the proposal provoked a good deal of misgiving in the General Assembly at Groningen in view of the difficulties of exchange which many European countries are experiencing. Members are to send their views to the Provisional Executive Committee before any irrevocable decision on the venue of the next congress is made.

It was hoped to have agreed the constitution of the new Federation at Amsterdam, but this proved to be impossible, and the existing Executive Committee was left in charge. One of the stalwarts of the old International Hospital Association, Dr. O. Binswanger, president of the Swiss Hospital Association, was elected vice-president of the Federation.

Some searching questions about the Federation's financial prospects were put at the final Assembly. The modest £5,000 a year needed ought not to be a major problem. Anyone interested in hospitals can become a member of the I.H.F. for 30s. a year, and out of all the many thousands of hospital workers in the world it ought not to be difficult to finance the Federation by individual subscriptions if Governments prove reluctant to contribute their share. Further information about the Federation can be obtained from Captain J. E. Stone, King Edward's Hospital Fund for London, 10, Old Jewry, London, E.C.2.

HARVEIAN SOCIETY DINNER

THE ARCHBISHOP OF CANTERBURY ON DOCTORS

The Buckston-Browne-Gray-Hill Dinner of the Harveian Society was held in the library of the Royal College of Surgeons on June 16 under the presidency of Dr. Desmond Macmanus. The health of the Society was proposed by the Archbishop of Canterbury, who said that his study of the history of the Society (founded in 1831) was not really a stimulus to oratory. At the time it was founded he noticed they were preoccupied with the problems of renal dropsy, the automatic reflexes of the spinal cord, and the discovery of the parasite of itch. They were also interested then in auscultation, and had only just succeeded in carrying the matter a stage further than Hippocrates did 2,000 years before. But now the advice and knowledge that the medical profession could offer and had was one of the astonishing wonders of modern times. "By your art," he said, "you have increased the expectation of life." Old people, it appeared, could go on living inordinately, and he wondered whether the medical profession in this respect had benefited mankind. "Are there," he asked, "enough young people to carry the burden of the old?" He hoped, however, that nothing would ever persuade the medical

profession to desert its cause of saving human life and to yield to the persuasion of those in favour of euthanasia. Nature he said, was a most ingenious person, and as fast as one disease was overcome Nature seemed to be able to put up another. "There is an active, intelligent adversary trying to defeat you." The advances in medicine made for increasing specialization. Every day the medical man tended to know more and more about less and less. To be an expert on a portion of a person made the specialist less capable of dealing with him as a human being. He was in favour of the old type of form master who taught the boy everything, and so, drawing this parallel, he was in favour of the general practitioner as someone who could treat the whole human being and refer to the expert only when he wanted an expert piece of knowledge or advice. Nowadays no science could live to itself. All sciences ran into each other. The atomic sciences were now becoming involved in ethics. Art, so he understood, could play an active part in healing. Religion also had a part to play in the healing of body and mind. Religion and medicine were beginning to understand they were necessary to each other, and he referred to the work already done by doctors and parsons together in the sphere of spiritual healing.

In response, Dr. Macmanus, the President of the Society, said that every third year it had a general practitioner in the chair. In the library in which they were dining there was on one side a bust of Harvey and on the other a bronze of Buckston Browne. Dr. Macmanus went on to draw an interesting picture of the conditions of travel in Harvey's day, noting that then, when travel was by horseback, a man had time and leisure to think, to write, and to read. In proposing the toasts of the guests Dr. R. P. K. Coe said that a parson had described the Archbishop of Canterbury to him as "a human bloke." Responding for the guests in appropriate and witty speeches were Vice-Admiral Sir Thomas Troubridge and Mr. Russell Vick, K.C. Among the distinguished gathering present were Sir Henry Dale, O.M., and Sir Alexander Fleming, F.R.S.

Preparations and Appliances

CONTINUOUS SUCTION: A NEW HYDRODYNAMIC METHOD

Mr. J. A. CARR, F.R.C.S., of the Preston Royal Infirmary, writes: Continuous suction has an established position in the treatment of gastro-intestinal cases, especially during the post-operative period, and in cases of intestinal obstruction. The

FIG. 1.—Special drip chamber with manometer.

FIG. 2.—Basic diagram.

method here described seems to have some advantages over older hydrodynamic methods.

Principle.—A fluid of low surface tension runs from a reservoir, at a rate controlled by a screw clip, to a dripper from which the drops enter a long tube, where the formation of a series of columns of fluid separated by air is assured by a loop. The weight of these columns causes them to descend and to

draw the interspersing air with them. If the apparatus is closed to the exterior a progressive reduction in pressure occurs, and this is used to aspirate the gastro-intestinal contents from the patient to a collecting-bottle. A mercury manometer indicates the fall in pressure, and the amount of mercury is so adjusted that when the reduction in pressure is equal to about 4 cm. of mercury all the mercury has been brought into one side of the manometer and air bubbles through. A reduction in pressure of 4 cm. of mercury is adequate for aspiration; a greater reduction produces an undesirable variation in the rate of the drip. Although this apparatus bears a superficial resemblance to Sprengel's pump it differs from it in that the pressure reduction is determined by the combined length of the columns of fluid and not by the pressure of the supply.

Apparatus.—An open-topped reservoir of 500-ml. capacity is used. The fluid is 25% spirit in water and is coloured with ink. The special drip chamber (Fig. 1) may be obtained from Messrs. Brady and Martin, Ltd., of Northumberland Road, Newcastle-upon-Tyne, 1, or the equivalent may be assembled from drip connexions, Y tubes, etc. (Fig. 2). The manometer, which is separate, has a bore of not less than 4 mm., or bubbling will not occur, and has a cotton-wool plug at each end to make the bubbling quiescent and to prevent loss of mercury. The descending tube should have a bore of about 2 mm.—translucent plastic tubing is better than rubber—and should be about 150 cm. long. There is no need for its end to be submerged. The coloured fluid is collected in a bottle and is used to refill the reservoir over and over again. The bottle to take the fluid from the patient has a capacity of about 500 ml. Care is taken to make all the bungs and connexions airtight, and to see that the cotton-wool plugs in the manometer are dry.

Use.—When the apparatus has been set up (Fig. 3) the fluid is allowed to drip through quickly until air is bubbling through the mercury. The airtightness of the apparatus is then tested by occluding the tube to the patient and stopping the drip. Leakage is shown by a gradual fall in the mercury level, and should be traced and prevented. The flow is then adjusted to about 30 drops a minutes, and is maintained at that rate.

Comparison With Other Methods.—Wangenstein's bottles and siphonage with an air trap have two particular disadvantages: first, the time at which they will require attention cannot be predicted; secondly, this attention is somewhat complicated. The new method works in the manner of a simple drip for infusion and needs the same attention. Satisfactory working in all cases depends on care in the original assembling of the apparatus.

This apparatus has been in routine use in the wards of the Preston Royal Infirmary for the past six months, and has proved both satisfactory and popular.

I would like to express my thanks to the numerous members of the staff of the Infirmary who have co-operated with me in the construction and use of this apparatus.

FIG. 3.—Assembled apparatus.

Owing to the difficulty of pricing the 170,000,000 prescriptions a year being issued under the National Health Service, the Ministry of Health has decided that from June onwards those with a net ingredient cost of 5s. and over (including prescriptions carrying special fees and D.D.A. and urgent fees) will be priced in full, while of those with a net ingredient cost of under 5s., 20% will be priced in full each month, the chemist being paid for the other 80% at his own average cost for the 20% fully priced. At present prescriptions with a net ingredient cost of over 2s. 6d. are fully priced, and 25% of those under 2s. 6d. The change has been made necessary because of lack of staff and accommodation, but the Minister is trying to increase the number of staff employed on this job.

Correspondence

Ogilvie's Syndrome

SIR,—Five cases of intestinal ileus due to sympathetic deprivation have now been described in the *Journal*. Both in Ogilvie's original case and in the later cases^{1,2} the interfering lesion was malignant invasion of the posterior abdominal wall. Although "Ogilvie's syndrome" has not been precisely defined, it is suggested that the essential feature is the production of intestinal ileus by sympathetic involvement rather than the malignant nature of the causative lesion. The following case is therefore suggested as an example of the condition, although the "invasion" of the posterior abdominal wall was due to a haemorrhagic, and not a neoplastic, process.

The patient, a man of 60 years, was submitted to herniotomy for a right inguinal hernia of two years' duration. The operation was performed under spinal anaesthesia. An indirect sac was found and excised. Immediate post-operative progress was uneventful, but on the fifth day he commenced vomiting copiously, and this continued with rapid deterioration of his general condition until death occurred 11 days after operation. During this time the patient was constipated, but passed much rectal faeces. Blood urea on the day preceding death was 364 mg. per 100 ml.

Post-mortem Findings.—The body was that of a very obese man, with a barrel-shaped chest and severe finger clubbing. The heart showed moderate left ventricular hypertrophy. The lungs showed terminal congestion and oedema superimposed on chronic bronchitis and emphysema. The pleural cavities were almost obliterated by old fibrous adhesions. A large extravasation of blood was present under the peritoneum throughout the lower half of the right anterior abdominal wall, spreading round into the posterior abdominal wall and also projecting downwards into the right side of the pelvis and passing upwards to form a large retroperitoneal haematoma 6 in. by 1.5 in. (15 by 3.75 cm.) in front of the right psoas sheath. The operation site appeared to be normal, there being no collection of blood in the subcutaneous, fascial, or muscular layers. The stomach showed slight congestion. The small intestine showed great dilatation of its entire length, with the exception of the terminal 6 in. (15 cm.) of ileum, which was involved in the extravasation into the posterior abdominal wall but which showed no organic obstruction. The colon showed moderate dilatation down to the lower sigmoid portion, the distension being gaseous, with only a small amount of faeces present. No twisting, bands, masses, stricture or faecal collections were present to account for organic obstruction.

This case occurred in June, 1947, before Ogilvie's syndrome was described. At this time the ileus was attributed to interference with the nerve supply to the intestine, but it was not decided whether this was due to sympathetic involvement by the haematoma of the posterior abdominal wall or to local interference with the nerves of the terminal part of the ileum which were directly involved in the extravasation. In view of the viability of the affected portion of gut and the absence of apparent interference with local blood supply it may be considered unlikely that the local nerves would have suffered selective mechanical damage, and it is now thought more probable that the "invasion" of the posterior abdominal wall by the haematoma might have been responsible for the ileus by a similar mechanism to that described by Ogilvie. Unfortunately no detailed dissection of the abdominal autonomic system was performed.—I am, etc.,

L. M. GERLIS.

Research in Renal Disease

SIR,—Writing as an obstetrician with a keen interest in renal problems, I wish to add to the support already given to Dr. Osman's major thesis (May 21, p. 910). Specializing in clinical nephrology is in general justified, (1) by the vastness of the subject and of its literature, and (2) by the wide prevalence and often serious character of renal disorder.

In my own particular field I have long been concerned with the renal changes of pregnancy, but despite extensive reading

and consultation with others I still lack final answers to many of my questions in the fields of renal anatomy, physiology, pathology, and so on. This experience, which I must share with many others, is in part due to the fact that there are few with sufficiently full time for the renal work, and in part to the fact that many gaps still remain in our knowledge which are all too slowly being closed by research.

An improvement can readily be made and maintained if knowledge is synthesized and further research encouraged in such a centre as, I imagine, Dr. Osman envisages. Then the lonely furrow which he himself has ploughed for so many years will be joined by several new ones, and the consequent harvest should be great. With all due deference I should like to suggest that the three Royal Colleges could find in the synthesis of knowledge about the kidney, and encouragement of research on the problems presented by it, a very worthy field for a joint effort. The synthesis of existing knowledge, as a beginning, could result in the production of a very much-needed book, in which the artificial separation of the three aspects of the subjects could be overcome in the ultimate interest of the patient. The encouragement of research would be a longer-term policy, but the initial consideration of it could be undertaken without much delay.—I am, etc.,

London, W.1.

JOHN SOPHIAN.

Death following Neostigmine

SIR,—In the cases described by Professor R. R. Macintosh (May 14, p. 852) and Dr. J. Clutton-Brock (June 4, p. 1007), though it was a mixture of neostigmine and atropine which was injected, death appears to have been attributed exclusively to the neostigmine. The atropine is presumably incorporated in such injections to diminish the cardiac and other untoward effects of the neostigmine. In fact, however, it is quite likely to do the reverse, and we feel that this should be pointed out.

Though we have no experience of intravenous atropine there is no doubt from numerous controlled experiments on healthy people that the primary effect of a subcutaneous dose of atropine sulphate (0.5 mg. per 50 kg. b/w) is to slow the pulse, sometimes very markedly, by what we have always supposed to be medullary (cardiac vagus centre) stimulation. This effect is well known to pharmacologists. It appears quickly and is at its maximum about 10–15 minutes after the injection. The pulse rate then either returns to normal and remains there, or it may rise significantly above normal for a variable period. The rise above normal is, of course, due to the peripheral blocking effect of the drug on the muscarinic action of the acetylcholine liberated by the tonic activity of the cardiac vagus : this effect, with the dose used, is usually slight.

Thus atropine administered subcutaneously first increases the effect of the cardiac vagus ; this action either ceases or, more likely, is masked by the subsequently established anti-acetylcholine effect of the drug. Though there is considerable individual variation in the degree of response in such experiments there can be no doubt about the sequence of events.

It therefore seems likely that a similar primary vagus stimulation with secondary partial vagus blocking may occur when atropine is given intravenously and that the primary effect in these circumstances would begin almost at once. If such central stimulation does occur on intravenous injection of atropine, then, clearly, its effects will be markedly potentiated by neostigmine. This would also apply to any central action of atropine tending to increase the tone of bronchiolar muscle. Hence atropine, administered simultaneously with neostigmine, far from preventing the unwanted effects of the latter drug may, at first, anyhow, be more likely to increase them. This may have been an important factor in causing death in the two cases cited.

Apart, however, from the possibility of such a potentiation of the effects of neostigmine arising from the central action of atropine, the peripheral anti-acetylcholine effects of therapeutic doses of atropine take some twenty or thirty minutes to be fully established. It is, therefore, not to be expected that the unwanted cardiac and bronchial action of neostigmine would be prevented by giving the atropine along with it. The importance of this point is increased by the known liability of both tubocurarine and neostigmine to produce bronchoconstriction by peripheral mechanisms.

The simultaneous intravenous administration of atropine and neostigmine would thus seem to be contraindicated on two grounds: first, that the atropine is likely by its central action to produce an immediate potentiation of the cardiac, and perhaps bronchiolar, effects of the neostigmine; and, secondly, that even if the atropine does not do this it is unlikely to produce an immediate antagonism of the unwanted peripheral effects of the other drug.—We are, etc.,

W. A. BAIN.

Paediatrics and Family Practice

SIR,—In the letter from Drs. S. D. M. Court and F. J. W. Miller (June 4, p. 1006) I note the sentence: "We are now trying to discover the amount and kind of disease in children encountered by practitioners in different kinds of practice, and Dr. Naish could probably help us on this point straight away." I would like to assure them at once that if there is any information in my notes that would be of use to them it is at their disposal. In addition, I am wondering what they mean by "different kinds of practice."

It is obvious, easy, and therefore usual, to classify practices according to the patients or to the milieu—uneducated/educated, rural/urban, etc. I grow more and more convinced that it is just as important to classify practices according to the outlook of the doctor. Whether by training, by temperament, or by the influence of individual teachers, doctors are as a rule definitely orientated either toward the maintenance of health or toward the cure of disease, and in a very short time they impose something of their own outlook on the practice they run. The one extreme, where feckless parents call one in frantic alarm to see cases of late disease, is not merely an uneducated practice, but an "uneducated-curative" practice. The other extreme, where responsible parents cope themselves with minor ailments and call one early when they are puzzled, is an "educated-preventive" practice.

I am uncertain in what order to place the two mediate items in this classification. During the war, however, I had charge of some evacuees from the East End of London who were obliged to occupy condemned premises and to rear their babies in the most unpromising circumstances. They did it extremely well, and produced some of the most careful and accurate records of home test-feeding I have ever seen. What "kind of practice" would Drs. Court and Miller consider these slum evacuees to constitute? In my nomenclature they would be an "uneducated-preventive" practice; and they lead me to think that possibly better results are to be expected from that than from an "educated-curative" practice.

To Dr. Rosefield's query in the same issue (June 4, p. 1006) about the regular attendance of children over one year, I would reply that possibly he is asking too much. I have only advised my mothers to bring the older children for examination about once in six months, and so far I have found them on the whole willing and able to do that. I must admit, however, that my experience of this problem is not nearly so long as his.—I am, etc.,

York

F. CHARLOTTE NAISH.

Diathermy Prong Forceps

SIR,—Mr. Wilson H. Hey (May 21, p. 911), during his long and distinguished career, has rendered surgery a great service.

He has been an inspiration to many surgeons, who owe him much for the benefit they have derived from his stimulating ideas and the example of his surgical skill. My debt is greater than most, for he has been my teacher, colleague, and friend; I shall never cease to be grateful for the privilege of my association with him.

One of his most outstanding contributions to surgery has been his constant advocacy of diathermy for sealing vessels during operations. The diathermy haemostat has not been widely used because no person published its advantages until I did so in 1944.¹ Our American colleagues who were over here during the war were so intrigued by the instrument I used that they persuaded me to make the idea more widely known; since when I have had requests from all over the world for reprints of my paper.

With regard to the specially designed diathermy haemostat, I have found in practice that it is neither as satisfactory nor as sound mechanically as the home-made instrument which I described. I base this conclusion on the following points:

1. In the home-made instrument the lead lies neatly and unobtrusively in the palm of the hand and there is no danger of its catching on the towels, etc., or hindering the movement of the fingers; it is completely under control.

2. (a) In the specially designed instrument the lead is connected to the periphery, where it acts as a constant obstruction to manipulation of the instrument and movement of the fingers. (b) On account of the protuberance of the attachment the patient is exposed to the danger of accidental burns. (c) The lead being attached at the extremity of the instrument it can exert a powerful leverage which tends to restrict manoeuvrability, usually at a moment when slickness is all-important. (d) The lead attachment screw sometimes works loose during sterilization or whilst in use, and might conceivably get lost in the patient's abdominal cavity.

With regard to the insulating tape used in the home-made instrument, this is only one layer deep and is not used to bind the junction to the haemostat but only to cover the bare wire to prevent damage to the surgeon's gloves. The insulating tape is prevented from becoming unstuck by overwinding with a length of cord or silk (any material will cover the junction equally well).

The question of sterility was raised by a colleague of mine some time ago and we made the following tests. After boiling we had cultures made of washings taken from beneath the tape. We found that in no case were any organisms grown in spite of our having smeared the depths of the tape with cultures of staphylococci, streptococci, and the spore-bearing bacilli. Fifteen cultures in all were made. For me this is proof that boiling is a satisfactory method of sterilization.

It is my earnest hope that this correspondence will encourage surgeons to test my diathermy instrument and those described by Mr. Wilson Hey (June 21, 1947, p. 897) and Mr. A. Wilfrid Adams (April 9, p. 631). When they have tried out the respective instruments it would be interesting to have their views. Only in this way can the greatest advancements in surgery be achieved.—I am, etc.,

Sheffield, 1

DAVID AIKEN.

Reliability of Laboratory Tests

SIR,—In your annotation on the reliability of laboratory tests (April 30, p. 766) you close with the statement, "If the results of any test are to be of value to the clinician, then the test must be able to detect differences smaller than those which are of clinical significance. It seems that not all laboratory tests meet this requirement, for some of them demand more skill than an average laboratory technician possesses." A close perusal of your remarks and of the paper by Biggs and MacMillan fails to reveal any foundation for such a statement regarding medical laboratory technicians in this country.

The systematic training received by medical laboratory technicians in this country and America was admirably compared and described by Whitehead (*Lancet*, 1949, 1, 113), together with a summary of the requirements for the diploma of the Institute of Medical Laboratory Technology. Although these requirements are approved and recognized by the majority of pathologists and employing bodies as a means of ensuring a reasonable standard of competence, unfortunately a few pathologists and official bodies appear to consider these requirements too ambitious.

In view of these facts, one feels that an explanation or some amplification of your concluding paragraph, quoted above, will remove any suspicions of an ill-conceived or biased review.—I am, etc.,

Stanmore, Middlesex.

R. J. BROMFIELD.

** No criticism of the work or training of laboratory technicians was intended in the annotation from which Mr. Bromfield quotes the final sentence. The point we wished to emphasize was that the reliability of the results of laboratory tests could be ensured by the use of methods which give the best results in the hands of the average laboratory worker.—ED., *B.M.J.*

Dried Plasma for Domiciliary Midwifery

SIR,—I have read with interest Dr. C. T. H. Whiteside's letter (June 4, p. 1005) on the above, and I feel that I must strike a note of warning. I agree that facilities for resuscitation of patients suffering from post-partum haemorrhage are important, but I feel very strongly that the use of dried plasma will do much more harm than good.

For some years now I have avoided the use of plasma, primarily because I have so often seen it fail. Apart from the dangers of jaundice, which an increasing volume of literature has shown to be very real, the fact is that plasma fails to resuscitate these patients. The woman who has lost blood in the third stage of labour requires above everything oxygen to maintain the integrity of the vital centres in the medulla, and this plasma cannot give her. It will increase the blood volume and perhaps produce a temporary improvement in the circulation, but this is only temporary and rather spurious, and again and again I have seen a secondary collapse from which it has been impossible to rescue the patient.

At a recent meeting of the Edinburgh Obstetrical Society Professor Kellar said that the use of plasma had been given up entirely at the Simpson Memorial Hospital and that in several of the cases on which it had been used unsuccessfully post-mortem examination had revealed suprarenal haemorrhages. Whilst a direct cause and effect association could not be substantiated, none the less, plasma had been entirely replaced by saline and whole blood.

In almost all parts of the country to-day "flying squads" are available in one form or another, with the resources of blood banks behind them, so that in any case where it is necessary it should be possible to undertake transfusion of blood in a comparatively short time, and the patient's condition in the meantime can be maintained if necessary with intravenous saline injections. This, unlike plasma, carries a negligible risk of infection and, moreover, again unlike plasma, is rapidly cleared from the circulation to make way for subsequent blood transfusion. The use of morphine also in these cases will help to delay the development of shock and tide the patient over until blood is available.

May I suggest, therefore, that Dr. Whiteside will find that his results will be much better if instead of plasma in his special bag he will carry two pints of normal saline and will make use where necessary of the emergency services in his area.—I am, etc.,

J. A. CHALMERS.

J. A. CHALMERS.

Surgery at the Front

SIR,—I have read the obituary of Mr. Owen W. Richards (May 21, p. 915), and I think you will find in the records that the first abdominal and chest unit in the forward area was opened by the 26th Field Ambulance, 8 Division, at Bac St. Maur, north-west of Merville, in early September, 1915.

In the winter of 1914-15 I suggested to our C.O., Lieut.-Col. A. Milne Thomson, C.M.G., that the abdominal cases were dying of haemorrhage, and that if operated upon in the forward area results would be better. He gave me permission to perform necropsies, which demonstrated that haemorrhage from the small mesenteric vessels was the chief trouble, in many cases only a small part of the bowel being perforated. First it was suggested that the necessary sterile materials should be sent forward in drums from No. 6 C.C.S., Merville, or the advanced depot of medical stores, as we had not space available in a mobile unit to transport autoclaves, etc. In January, 1915, by permission, I called at the War Office, and on explaining our difficulties was issued with various instruments. In early September, 1915, our unit was moved to a factory in Bac St. Maur, where, besides opening our usual dressing station, etc., Col. Skinner, D.D.M.S. 3rd Corps, ordered us to prepare for an operating unit.

The main weaving shed of the factory had central heating, electric light, and much machinery in it; a portion sufficient for 30 beds was sectioned off by green hessian canvas. An operating room was prepared in a corner of the next shed near a large window. Lieut. J. Fraser, later Sir John Fraser, was attached to us as surgeon, and four nursing sisters also, one a regular. Shortly afterwards Lieut. Fraser was sent to another area and Lieut. Sampson (now a Birmingham surgeon) took his place. This factory was about 5,000 yards from the

front trench, and I believe Col. Skinner had some difficulty in persuading higher authority to allow sisters so near the front.

The abdominal and chest cases were admitted from the whole Corps area, and when fit to move were transported by barge (specially equipped) to St. Omer and the sea. In spite of absence of blood transfusion successful results were obtained at first in 27%, then up to 47%, of all cases operated upon. In February, 1916, the factory was heavily shelled—glass and debris flying in the operating room where an operation was being performed. Of the only three officers of the unit available Lieut. Samson was operating, I (acting O.C.) was assisting, and Lieut. Henry was giving the anaesthetic, so it was fortunate that Col. Skinner was visiting at the time and could at once arrange for the urgent evacuation of the movable cases to a farm 300 yards away. Later, the whole unit moved with the 8th Division to another area. Probably this experience resulted in the higher command not allowing nurses so far forward at a later date. Great praise and thanks were given to the unit for the way in which all ranks carried on the work of the special ward, and for the way in which the movable cases were evacuated, by the A.D.M.S., the D.D.M.S., and the D.M.S. 1st Army. Lieut. Samson received the M.C., and the regular sister in charge of the ward and the operating theatre sister received the R.R.C.

Among the interesting cases were the following: one fore-and-aft penetrating bullet wound of the abdomen, not injuring the bowel and with practically no bleeding; the other a 10-in. (25-cm.) accidental bayonet wound of the abdominal wall, through and through but not entering the peritoneal cavity.—I am, etc.,

Mentoue, France.

E. ALDERSON.

Women War Captives in Russia

SIR,—With reference to the article entitled "Women War Captives in Russia" by Dr. R. F. A. Dean (April 23, p. 691) concerning the conditions of life of German women in labour camps in the U.S.S.R., I should like to add a few remarks from my own experience.

As a member of the Polish underground army I was deported to Russia in April, 1945, and I stayed in various camps until November, 1947. I found myself among prisoners of war of many nationalities, as well as in camps with a majority of German civilians. I can fully support the evidence given by the said German women, but I should like to point out that no definite and general conclusions can be drawn from such evidence as to conditions prevailing in Russian camps. These conditions vary considerably, not only according to different geographical and local circumstances, but, above all, they depend on the attitude of the Soviet authorities towards the given group of prisoners at the given moment. The German women described in your article were lucky to find themselves in mild circumstances. They estimate the number of deaths in transport on their way to Russia as 2% to 2½% only. This percentage can be increased twenty-fold and still remain true: in the summer of 1945 I personally took part in a medical examination of a group of about 1,000 Estonians who came to Stalinogorsk Camp on their way from East Prussia to central Russia. They had walked about 800 miles, and the death rate among them was over 50%.—I am, etc.,

Wembley, Middlesex.

MIECZYSLAW PESZCZYNSKI.

Threatened Abortion Simulating Ectopic Gestation

SIR,—The following case is reported to illustrate how regurgitation of blood into the Fallopian tubes in threatened abortion may simulate ectopic gestation.

A patient, aged 23, para 2, was admitted to hospital on April 20, 1949, complaining of lower abdominal pain following seven weeks' amenorrhoea, the last menstrual period being on Feb. 22, 1949. The periods had previously been quite regular and of normal amount. On March 7 she had a slight show of dark blood lasting one day, and another show lasting three days immediately prior to admission. The lower abdominal pains, which were mainly in the left iliac fossa, had been present on and off for one month, and she described them as period pains which had now become severe. There had been no vomiting or dysuria.

Abdominal palpation showed generalized tenderness in the lower abdomen, with well-marked guarding in the left iliac fossa. Per vaginam some dark blood was visible, the cervical os was closed,

and movements of the cervix caused severe pain. Bimanual examination of the uterus, which was difficult because of extreme tenderness, showed the uterus to be only slightly enlarged. The right fornix was normal, and on palpation of the left fornix the presence of a small mass was suggested; this was too painful to be accurately defined. Her temperature was 98.4° F. (36.9° C.); pulse 80, blood pressure 120/70. There were no abnormalities in the urine. In view of the history, her lower abdominal pain, and the marked tenderness on vaginal examination, it was decided she was a case of left tubal gestation, and laparotomy was performed on April 20. On opening the abdomen, the uterus appeared to be about 8-10 weeks pregnant; no ectopic pregnancy could be found, but about 2 oz. (57 ml.) of altered blood was noticed in the pouch of Douglas. Careful inspection of the left Fallopian tube showed it to be not enlarged, injected, or swollen, but of a beaded appearance and dark blue in colour due to the lumen being intermittently distended with blood. On milking the tube about 2-3 ml. of dark blood oozed from the abdominal ostium. The right tube appeared normal, but on milking it towards the abdominal ostium two or three drops of dark blood were also produced. The ovaries appeared normal. The pouch of Douglas was mopped out and a normal appendix removed before closing the abdomen.

The patient had a slight loss of blood per vaginam the day following operation, but convalescence was otherwise uneventful. There has been no recurrence of her abdominal pain, and the pregnancy is continuing satisfactory to date.

I consider this patient to be a case of threatened abortion with regurgitation of blood into the Fallopian tubes, causing distension of the lumen and hence producing symptoms and physical signs identical with an early ectopic gestation.—I am, etc.,

Stoke-on-Trent.

H. D. FREETH.

Breast-feeding

SIR,—The modern decline in breast-feeding is commonly attributed either to the ignorance or to the apathy of the family doctor. Many of us, who frequently condone the action of the distraught or unwilling mother in "putting the baby on the bottle," feel that our argument for breast-feeding lacks conviction, knowing the high incidence of breast infection. In recent years breast-feeding has undoubtedly carried with it a considerable hazard to health. In spite of penicillin and sulphonamide therapy breast abscess still occurs too frequently, and we are certainly ignorant of how it does occur.

It was with this problem in mind that I read Dr. F. Charlotte Naish's admirable book, *Breast Feeding*. In discussing mastitis and its prevention, Dr. Naish (pp. 63 and 127) refers to the value to be derived from the study of dairying methods. It appears doubtful, however, whether Dr. Naish and her farmer's wife are referring to the same disease process. The "milk fever" of the dairy farmer has no relation to mastitis, and, to the best of my knowledge, the blood-calcium depletion seen by the veterinary surgeon in "milk fever" has no counterpart in medical practice. The validity of Dr. Naish's deductions is therefore in question, however successful she has been empirically. Dr. Naish has done a notable service in showing what can be done in general practice. It is admiration for her work that has prompted me to point out this flaw in its excellence.—I am, etc.,

Thornton, Fife.

JAMES B. FLEMING.

"Cord Round the Neck"

SIR,—Further to my letter in the *Journal* of May 4, 1946 (p. 701), I have again observed this abnormality in the same multipara with the history of two stillbirths.

The patient (7-para) was delivered on Nov. 4, 1944, by forceps under chloroform of a stillborn female, death being caused by torsion of the cord. On March 29, 1946, she delivered naturally a stillborn male; again death was caused by the cord round the neck. On Sept. 21, 1947, she gave birth to a live-born male child without this abnormality. On June 3, 1949, a stillborn female child was born naturally with the cord round the neck. Again the child had been strangled.

I venture to suggest that delay in the second stage associated with foetal distress may be attributable to cord round the neck, and, where suspected, should be treated by early caesarean section to ensure a live child.

My thanks are due to Dr. Archibald Neville McLellan for help with this patient.

—I am, etc.,

Harthill, Lanarkshire.

S. H. P. McLAUCHLAN.

Fatal Myelitis after Antirabic Vaccine

SIR,—Dr. I. Ansell (Aug. 14, 1948, p. 338), describing a fatal case of myelitis after antirabic vaccine, concludes that "antirabic treatment should be given only when the correct indications are present. A healthy dog should be kept under observation for the usual ten days before treatment is begun, except possibly in cases of severe bites on the face."

As far as I am aware, it is still the practice in most centres responsible for treating persons bitten by dogs and other animals not to wait until the disease declares itself in the dog before commencing treatment, for the reason that, although the virus is believed to reach the brain via the nerves, the time it takes to do so varies over wide limits (days, weeks, or months). Consequently it seems to me that as this rate of travel of the virus can only be guessed at in the majority of cases the withholding of treatment for some days may amount to jeopardizing the life of the patient, who has no chance of surviving once the disease does develop.

Since the incidence of neuromuscular accidents following antirabic vaccine is one in many thousands and the mortality from all types about 25%, I cannot help feeling that Dr. Ansell's conclusion is likely to be misleading, and almost comparable to advising a patient not to undergo what might prove to be a life-saving operation merely because one person in many thousands dies unexpectedly during the induction of the anaesthetic.

I would welcome your opinion on this point, which I feel is important, because so few practitioners have a clear idea of what should best be done in bites from animals. Rabies is a disease in which one cannot afford to take a chance.—I am, etc.,

Hong Kong.

Thiosemicarbazone

SIR,—The letter from Dr. L. Fish (June 4, p. 1005), together with your note following it, is timely. Perhaps the readers would be interested to hear that a whole day was devoted to the chemotherapy of tuberculosis at the recent Congress of Internal Medicine at Wiesbaden, which I attended. The treatment of pulmonary disease by thiosemicarbazone held an extremely prominent place in the papers and discussions, which were initiated by Professor Domagk from the pharmacological aspect and Professor Heilmeyer from the pathological aspect.

Apart from the general work on this group of substances (which are directly derived from sulphonamides), the only reference I know to its use has been in a lecture given in New York in June, 1948, by Dr. D'Arcy Hart.

The Germans place these drugs—mainly one which they call "T.B.1"—midway between streptomycin and para-aminosalicylic acid in their chemotherapeutic efficiency, and it would seem that very much work is needed to be done in this country on the subject if our armamentarium in the treatment of tuberculosis is to be completed. It is proposed shortly to do a small clinical trial with thiosemicarbazone if arrangements for its supply can be adequately made, and this will be the subject of a future communication.—I am, etc.,

London, S.E.12.

M. M. NAGLEY.

Routine Medical Examinations

SIR,—With reference to Dr. R. Frank Guymer's letter on routine medical examinations (June 4, p. 1007) and the application of Pulheems to industry, I am sure Dr. Guymer would be interested to know that we have been applying this system at Messrs. Taylor Woods, Ltd., Hosiery Factory, Enniskillen, for two years. In conjunction with the personnel department a series of profiles for the various jobs have been made.

We find that the system is almost an essential, as some of the jobs are very highly skilled and long periods of training necessary. We believe it has helped to avoid labour turnover and absenteeism. Three hundred and fifty potential employees have been examined up to the present. This number we consider insufficient, but when the 500 is reached we hope to have some figures to substantiate our belief in this system as applied to industry.—I am, etc.,

Enniskillen, Co. Fermanagh.

HAROLD K. ARMSTRONG.

Marriage Guidance by Doctors

SIR,—At the Conference on Marriage Guidance held recently at Scarborough I urged the training of doctors in sex problems, and, as rather garbled versions of my remarks have appeared in the Press, may I restate the position, and suggest a possible solution?

A recent annotation in the *Lancet*¹ commented on the lack of sex education given to medical students to-day. It is a fact that in most medical schools no teaching whatever is given on the technique of sex, on contraception, on abnormal psychology, on pre-marital advice, or on marriage guidance. The student's general training is based on disease of organs and not on dysfunction of the individual—still less so when it affects two individuals composing the single entity of a marriage.

Most doctors who have acquired any knowledge of sex by the time they graduate do so not by any organized instruction on the subject but by private enterprise. When patients seek advice on these subjects the doctor is in a dilemma, because not only is his knowledge inadequate, but, worse still, he may have inhibitions about the subject. As a result it is not surprising that Stallworthy and Green-Armytage² can quote 4–5% of all cases attending sterility clinics as being *virgo intacta*—a figure which I can confirm from my own clinic.

The following other examples are illustrative of inadequate or wrong advice:

(1) A woman was referred for leucorrhoea. I removed a foul object, which proved to be an unrolled washable condom. She explained that she had been advised at another hospital not to have more children. The R.S.O. said her own doctor would advise, who in turn suggested that her husband go to the chemist and he would advise. The chemist merely handed over the sheath, and, not knowing what to do with it, this pathetic couple decided that the vagina was the correct place in which to put it.

(2) In two cases referred on account of sterility each patient had had curettage under anaesthesia elsewhere, without the gynaecologist realizing that she was *virgo intacta* and that he was the first to rupture the hymen. After suitable advice each became pregnant.

(3) In several other cases girls requesting pre-marital examination had been told elsewhere to have excision of the hymen. Seeking a second opinion before risking an anaesthetic and operation, I was consulted and advised digital self-dilatation, which in a period of about 10 days produced an adequate result. Such advice as these girls had previously received might be tragic—and yet it is a common happening to those who know of the ignorance and general reluctance of doctors to deal with these problems adequately.

It is realized that not all doctors are temperamentally suited for this type of work. Nevertheless all medical students should be given sufficient basic training to enable them to recognize the nature of the problems which may confront them later, and know where to send such people, even though they themselves may never wish to undertake treatment. The present overcrowding of surgeries deters even those few who are interested from dealing with such cases.

The answer to this problem must be provided in special centres at which such work could be undertaken by those fitted for it, and training centres for doctors also established there in circumstances where the time available per case would be adequate. This would also overcome the ethical problem of a doctor who does marriage guidance work being accused of poaching on his colleagues' patients if he sees them at his own surgery. It also leads to the conclusion that doctors in charge of such centres should have special training in marriage counselling, organized and approved by a body of established authority. Such a body would appear to be the National Marriage Guidance Council, which has already worked out a technique of training and has the experience in this field of work to appreciate the difficulties. Most emphatically the organization of training at and staffing of such centres is not a function for a hospital board, local authority, or government department; it is highly delicate work, requiring special qualities in both the training and personality of the doctor.

The problem is an urgent one, and I would urge the immediate calling together of a conference of interested parties, perhaps under the auspices of the National Marriage Guidance Council, to study the possible solutions.—I am, etc.,

Manchester, 8.

London Lock Hospital

SIR,—We must all join with your correspondent, Dr. Raymond Oliver (June 4, p. 1004), in regretting the possible disappearance of the London Lock Hospital in its present form. Apart from his letter, the medical press has seen a number of letters and editorial articles to the same effect since the North-West Metropolitan Regional Hospital Board made public recently the recommendation that it has under consideration to transfer the buildings of the Lock Hospital to the West End Hospital for Diseases of the Nervous System.

Such "change of user" of hospital premises will no doubt take place not infrequently throughout the country as the regional boards consolidate and co-ordinate their hospital services; these changes are inevitable with the declining demand for some types of hospital and the maintained or even increasing demand for other types. It is a great social gain that modern therapy has made in-patient treatment in venereology less necessary than hitherto, though it is sad to see as a consequence the need for famous institutions in their old forms pass away; we find this sad just as our great-grandfathers found the inevitable disappearance of the sailing ship and the stage coach equally sad and equally difficult to accept.

Venereology is not the only branch of medicine to find to-day less need for beds; there has been a similar sudden collapse in the demand for fever-hospital beds. Whilst the fever hospitals are now turning over a high percentage of their beds to other work, we may spare a pang of regret for the practitioners of this branch whose field of future work and interest has so suddenly contracted.

In regretting the changes necessary in some institutions do not let us forget the pressing need of those for whom a demand continues and who may have less resources than before to meet it. That the needs of the West End Hospital for Diseases of the Nervous System have been under consideration by the North-West Metropolitan Regional Hospital Board has been made public. Little attention has been paid in the medical press to the serious position of this hospital and its work. Before the last war this hospital for organic diseases of the nervous system was working in central London to the limit of its capacity in neurology and neurosurgery, for the practice of which there are certainly not too many beds in London. The hospital was divided into two parts—out-patients in Welbeck Street and in-patients in Regent's Park—and its war risks may have been thought to have been minimized by such "dispersal." However, in 1940 its out-patient premises received a direct hit, with severe damage, loss of life, and injuries to members of its staff. It has not been possible to repair this damage since, and only a small portion of the out-patient department is now working (still to capacity). The in-patient department, standing isolated in Regent's Park, was totally destroyed in 1944 by a flying bomb, with heavy loss of life among patients and staff, and it has not since been rebuilt. The demand for this hospital's work has nevertheless continued unabated, and the work has had to be carried out under very difficult conditions—for example, in beds borrowed from other hospitals.

Whilst we may shed a tear for the Lock Hospital, whose needs have lessened, what must our feelings be for the West End Hospital, whose tragic damage, in the opinion of a Ministry of Health architect, was relatively greater than that of any other hospital in London? If the Lock Hospital buildings are used to meet such a necessity, then those with an affection for this hospital should be consoled by the realization that the buildings will be serving a purpose as high and as valuable as heretofore.—I am, etc.,

London, W.1.

T. ROWLAND HILL.

POINTS FROM LETTERS

Treatment of Varicose Veins

Dr. J. W. HAUGHTON (Truro) writes: I was very glad to see Dr. R. Simpson Harvey's letter (June 4, p. 1005). I had a large number of cases (over 200) when I was surgeon at the Falmouth Military Hospital during the first war. I found, if I emptied the vein by elevating the limb, applied a light tourniquet at the upper end, injected a large amount of sclerosing fluid and gently forced it into the vein, that I got best results.

Obituary

SIR JAMES PURVES-STEWART, K.C.M.G., C.B.,
M.D., F.R.C.P.

Sir James Purves-Stewart, the well-known neurologist, died at his home in London on June 14 at the age of 79. The son of Mr. John Stewart, J.P., of Edinburgh, he was educated at the Royal High School of the city. He won many medals and prizes as a medical student at Edinburgh University, and graduated M.B., C.M., with first-class honours, in 1894. After holding resident posts in the Royal Infirmary his unusual ability led to his appointment as assistant, first to the professor of physiology and later to the professor of medicine. Stewart, as he was then, began at this early

(Elliott and Fry, Ltd)

date to publish papers on various subjects, including one on the superficial anatomy of the nerves. A happily successful guess in 1895 about the location of a cerebellar tumour encouraged him, so he recounted in the preface to one of his books, to launch into the great stream of neurology. After proceeding M.D. in 1897 he left Edinburgh for London, where he was for two years a resident house-physician at the National Hospital for Nervous Diseases. At Edinburgh he had acquired a sound knowledge of physio-

logy and medicine. At Queen Square he began to build on this foundation a specialized experience of neurology.

As physician to the Imperial Yeomanry Field Hospital, Stewart was mentioned in dispatches for his services in the South African campaign of 1900-1. When this war was over he visited the medical schools at Jena and Frankfurt. Returning to London, he was appointed honorary assistant physician to the Westminster Hospital. There he resumed teaching, first in pharmacology and therapeutics, later as lecturer on his chosen specialty of diseases of the nervous system. Soon afterwards he became known beyond the bounds of the Westminster Hospital with the publication in 1906 of his book *The Diagnosis of Nervous Diseases*. In the preface to the first edition he wrote: "It is seldom in medicine that we meet with diseases in their typical forms, at least as described in textbooks. More often we have to deal with patients who exhibit signs and symptoms common to several diseases. The present volume approaches the subject of diagnosis of nervous diseases from the clinical standpoint. . . ." This book was made up chiefly of lectures given to students and graduates, with reprints of articles in various journals and many illustrations. It broke new ground and was so well received that a second edition was called for in 1909 and a third by 1911. Each edition was freshened with new material and illustrations. French, German, Spanish, and even Arabic translations were called for. During the recent war, while in the U.S.A., he persuaded the well-known Boston neurologist, Dr. H. R. Viets, to help him in revising the book. Together they worked on it throughout each day for three weeks. The result of this thorough revision was sent to England by ship and through an accident of war was unfortunately lost for ever in the Atlantic Ocean.

During the 1914-18 war Stewart served in Malta, Gallipoli, Salonika, and Egypt. He was consulting physician to the Forces in the Mediterranean and Near East theatres. He was three times mentioned in dispatches, and was awarded the C.B. in 1916 and created K.C.M.G. in 1918. In 1927 he published a work on *Intracranial Tumours*, in which he recorded his experience of 253 cases, of which 121 came to necropsy. He confined his notes entirely to his own observations, and gave no reference to the work of other clinicians. This particular book was later translated into Russian. Sir James Purves-Stewart was also responsible for the neurological volume in the "Oxford Medicine" series, and for twenty-six years he wrote the section on nervous diseases for the *Medical Annual*. Apart from his work at the Westminster Hospital he was honorary physician to the West End Hospital for Nervous Diseases, the Royal National Orthopaedic Hospital, the Central London Throat and Ear Hospital, and the King Edward VII Convalescent Home for Officers at Osborne.

In 1930 Purves-Stewart was intimately concerned with the report of the discovery by Miss Kathleen Chevassut of a virus in the cerebrospinal fluid of cases of disseminated sclerosis. Purves-Stewart gave his own account of the investigations, which had been going on for two years in the Westminster Hospital laboratories. He claimed that the "virus," *Spherula insularis*, was found in 176 of 189 cases of disseminated sclerosis. He also stated that he had treated patients with a vaccine and that improvement had taken place in 40 out of 70 of these cases. He pointed out, however, the fact that patients with this disease often had spontaneous remission. Later he published another paper, in collaboration with Braxton Hicks and Hocking, describing inoculation experiments on animals. These studies created much interest but were sharply criticized. So important would the discovery have been, if confirmed, that offers were made by the Medical Research Council and the Halley Stewart Trust to defray the cost of repetition of the work in other laboratories. In February, 1931, Purves-Stewart dissociated himself from Miss Chevassut, because of her refusal in December, 1930, to repeat the original observations for the Medical Research Council. She did accept, however, premises and facilities offered by the Halley Stewart Trust, and 162 cases were treated there. The results in 69 of these cases were reviewed by Dr. F. M. R. Walshe, who concluded that patients so treated were worse off than if they had been left alone. By September, 1931, Miss Chevassut claimed that the specific organism could readily be maintained in subcultures on solid media. The Trustees, reasonably enough, wished to examine these cultures, but none were forthcoming. Finally in March, 1932, the Trustees had no alternative but to abandon the trial and close the small institute they had made available for this work. Subsequently Dr. B. Halley Stewart (*B.M.J.*, 1932, 2, 326) described how the organisms originally said to be present in 93% of cases of disseminated sclerosis were detected by their discoverer less and less often. Subcultures of the "specific organism" were also identified as pure cultures of the virus of bovine pleuropneumonia. Describing his uncongenial task, Dr. Halley Stewart mentioned that in her original paper on the subject Miss Chevassut had described her virus as bearing a striking resemblance to that of bovine pleuropneumonia.

Sir James Purves-Stewart was elected a Fellow of the Royal College of Physicians of London in 1906 and acted as examiner in medicine in 1904-8 and 1922-6. At annual meetings of the B.M.A. he served as secretary in 1912, vice-president in 1922, and president in 1931 of the Section of Neurology. He was a member of several American and Continental Societies and the recipient of many scientific

honours. He was always proud of his honorary rank of colonel, and at the age of 72 he contrived to serve in the Home Guard in the recent war, writing at that time his book *Over Military Age*. He made his home for many years of his retirement at the Belle Tout lighthouse on Beachy Head. Only last year he generously offered to present the lighthouse to the Eastbourne Corporation.

Purves-Stewart was very much of an individualist, and not free from the weaknesses common to lesser and greater men than himself. Among those who followed the same specialty in this country he occupied rather an isolated position. His enduring monument is his well-known and much used textbook, unique in neurological literature and of high value to those trying to master the most difficult of all medical arts, the diagnosis of diseases of the nervous system.

C. C. EASTERBROOK, M.D., F.R.C.P.Ed.

Dr. C. C. Easterbrook, who died in Edinburgh on June 5 at the age of 82, was for many years physician-superintendent of the Crichton Royal Institution, Dumfries.

Charles Cromhall Easterbrook was educated at George Watson's College, Edinburgh, and at Edinburgh University, where he graduated M.A. in 1887 and M.B., Ch.B. with first-class honours in 1892. He was a house-surgeon at the Royal Maternity Hospital and at the Royal Infirmary, house-physician at the Royal Infirmary and at the City Fever Hospital. He started his psychiatric career in 1894 under the late Sir Thomas Clouston, and for more than seven years he was on the staff of the Royal Edinburgh Mental Hospital at Morningside. He proceeded M.D. with honours in 1900 and became a member of the Royal College of Physicians of Edinburgh in the same year. He was elected a Fellow in 1903, a year after he had been appointed medical superintendent of the Ayr District Asylum. At Ayr he was responsible for considerable extensions to the hospital, and these included a new reception hospital and infirmary which he designed.

Dr. Easterbrook was appointed physician-superintendent of the Crichton Royal, Dumfries, in 1908, and held this appointment for 29 years, until his retirement in 1937. Under his leadership the Crichton not only retained its position among the foremost of psychiatric institutions but enhanced its reputation.

The Crichton had grown very considerably under his predecessor Dr. Rutherford, and one of Dr. Easterbrook's earliest tasks was to put before his board of directors a plan for the future development of the institution, aimed at making possible an ideal classification of the patients and, incidentally, nearly doubling the bed accommodation. The last building of the scheme he submitted as far back as 1909 was not completed until 1938. The directors did him the honour of naming this building after him, and Easterbrook Hall will remain a fitting memorial to his lifelong devotion to the mental invalid. The operating theatre and x-ray room, departments for hydrotherapy, physiotherapy, and occupational therapy, a swimming-pool, gymnasium, concert hall, café, library, and even a hair-dressing saloon all show the foresight of the man who planned all these things so many years ago. He was to a large extent his own architect, and in his buildings he incorporated all that he had found best in the Continental mental hospitals and clinics. Dr. Easterbrook made many contributions to the literature, and in 1925 he delivered the Morison Lectures to the Royal College of Physicians of Edinburgh, choosing as his subject "Mental Invalids." After his retirement in 1937, as a labour of love he compiled the *Chronicle of the Crichton Royal*, a comprehensive review of the growth and activities of the hospital throughout the century from its inauguration in 1837.

Dr. Easterbrook married in 1905 Ann Elliot Thomson, daughter of the late William Thomson, of Clovensford, Selkirkshire, and she survives him with a son and daughter.

Professor R. J. A. Berry writes: The death, after a long crippling illness bravely borne to the end, of Dr. C. C. Easterbrook has deprived the mental service of Scotland of one of its great personalities.

His memory will last, I take it, as long and even longer than the Easterbrook Hall at the Crichton Royal Institution. But it is not for his work that I lament his passing. It is rather for those personal qualities which so endeared him to contemporaries who knew him as intimately as I did. On Jan. 19, 1900, there met together at 21, Heriot Row, Edinburgh, and for the first time, seven young Edinburgh medical graduates, who then and there formed themselves into a small literary club which they termed the Heptagon. Meeting at each others' houses during the winter session, it was the duty of the host to provide the mental and physical pabulum for the evening, the whole bonded and cemented together by the best of friendships. Charlie's death confronts the writer with the melancholy fact that of the original seven members he is now the only survivor. But there must surely be some who have memories of Andrew Balfour, J. W. Dowden, C. C. Easterbrook, J. S. Fowler, C. B. Ker, and A. Logan Turner. It was Balfour, the Sir Andrew of a later day but then known to us as "Beefy," who read the first of the Heptagon papers on Graham's *The Social Life of Scotland in the Eighteenth Century*. And now Charles Easterbrook, too, has gone.

Dr. ISAAC FLETCHER died at his home in Workington, Cumberland, on May 28, at the age of 85. He was born at Seaton, close to the town of Workington where he practised for sixty years. He graduated M.B., C.M. at Glasgow in 1890, took the D.P.H., and soon settled down to a long life in general practice. He always worked hard, but he crowded many other interests into what little spare time he had. He was essentially a family man, and was very happy to see his five sons carrying on the best traditions of the medical and dental professions, while his daughter formed the last link in a strongly united family circle. As would be expected, his hobbies were directly concerned with the welfare of others: he was an exceptionally keen worker in the St. John Ambulance Brigade, a Rotarian, and a Freemason, and he reached the highest ranks in all these brotherhoods. He was, too, a life-long teetotaler and non-smoker, and never ceased to support the temperance cause. Dr. Isaac Fletcher had little time to spend on games, but he was a keen Rugby Union footballer as a young man, and he ultimately became life president of the Cumberland Rugby League. He was not a big man physically but kept his trim figure all through his life. He was no motorist, and cycled his rounds practically up to the last. His capacity for life in all its aspects was immense—for example, in the first world war he looked after three practices, acted as school medical officer, and sat on recruiting boards. He practised for many years in the days when the G.P. had to deal with everything which came his way; major surgery, obstetric emergencies, and anaesthetics were all part of his daily routine. He was an artist in the use of chloroform, and his records with that anaesthetic will stand comparison surprisingly well with those of its modern counterparts. An outstandingly able example of the old type of doctor giving devoted and excellent service to the community, Dr. Isaac Fletcher was a kindly man, and his colleagues never hesitated to turn to him for help. A wise man, too, his counsel on any problem was worth having, and the dividing line between right and wrong was clear as crystal to him. The crowded church and the hosts of mourners at the graveside showed how great was the affection and respect felt for a man who had long outlived his generation, and yet died in the midst of a community which loved him and which will miss him as no other man in Workington could be missed.—A. G. A.

Medico-Legal

USE OF TITLE M.D.

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

Section 40 of the Medical Act, 1858, does not forbid practice by the unqualified, but attempts to enable the public to distinguish between qualified and unqualified practitioners. It prescribes penalties for the offence of wilfully and falsely using certain well-recognized titles, of which doctor of medicine is one, or any description implying that the user is registered under the Act. Doubt had always existed until recently whether a practitioner who has the degree of doctor of medicine of a reputable foreign university but is not on the British Medical Register commits an offence if he uses that title. When a recent prosecution brought the question before the High Court for decision, the Lord Chief Justice considered it so important that he convened a full King's Bench Divisional Court of five judges to hear it argued.

Dr. William Luftig was originally Austrian, and obtained the degree of M.D. of Berlin University in 1913. He said that he became a British subject by naturalization in 1938 and practised in London and Northampton and from 1944 in Brighton, where he specialized in ophthalmology. He originally used on his plate the description "M.D. Berlin," but after he had received threatening letters and had had swastikas painted on his house he adopted the abbreviation "BLN." He had written four books in English on eye diseases, and in these he is described as "William Luftig, M.D.," with the addition underneath in small lettering of the words "Graduate of the University of Berlin." He was not on the British Register, although he could have applied for registration under the Defence (General) Regulations, 1939. Mr. Thomas Stanley Younghusband, on behalf of the Medical Defence Union, preferred an information against him before the Brighton justices alleging that on May 25, 1948, and subsequently, he falsely used the title of doctor of medicine and the description M.D., thereby implying that he was registered under the Act of 1858. The justices held that no offence against Section 40 had been committed and that the use of the letters M.D. BLN did not imply that he was registered. The prosecutor appealed to the High Court.

The case for the prosecution, argued by Mr. Cecil Havers, K.C., was that Dr. Luftig was not a doctor of medicine within the meaning of the Act, and that, if that were so, he had contravened the section by wilfully and falsely using the letters M.D. after his name; that the use of those letters implied that he was registered under the Act of 1858 and that, as he was not, that use constituted a similar contravention of Section 40; that the initials BLN were unknown in this country as an abbreviation for Berlin and there was no evidence that they were so known elsewhere; that BLN by itself was meaningless and implied that Dr. Luftig held a separate degree so described, and that M.D. stood alone and meant that he was an English doctor of medicine registered under the Act. Mr. Havers submitted that it was unlawful for anyone to use the letters M.D. unless he was a registered medical practitioner or possessed a qualification entitling him to be registered. It would not have been sufficient to avoid an offence if Dr. Luftig had used the full word Berlin after the M.D. Alternatively, there would have been no offence in his description of himself had he not engaged in the practice of medicine.

Mr. D. E. Evans, who appeared for Dr. Luftig, submitted that the true construction of Section 40 was that it prohibited the use wilfully and falsely of any of the specified well-known descriptions by someone who had no right or title or claim to them. That was not so in this case, for Dr. Luftig held the qualification of a recognized foreign university. If a man had a genuine degree in medicine of a well-known university he committed no offence under the Act if he described himself as M.D., even if he did not add any indication such as "Berlin" or "New York," for he had said nothing that was false. Dr. Luftig had used the letters BLN in order to avoid drawing unnecessary attention to his former nationality. His motive was not related to extending his practice or to defrauding the public in relation to his right to practise.

The Court's Judgment

The court reserved its judgment for a week, and the Lord Chief Justice, reading it, said that there was no doubt that the justices had considered that the diploma produced by Dr. Luftig was a diploma granted by a genuine university. The term "doctor" was now commonly used to mean any medical practitioner, but when it was used in conjunction with some particular branch of learning it meant one who in any faculty had attained to the highest degree conferred by a university. A person who described himself as a doctor of medicine represented that he had had that degree conferred on him by a university as the result of competent examination. The courts would know how to handle an imposture consisting of the use of the description doctor of medicine on the strength of a piece of parchment and a hood bought from some commercial concern. The Medical Act of 1886, providing for reciprocity with foreign universities, did not apply in the present case because it had never been applied by Order in Council to Germany. Much of the difficulty surrounding the present question came from the opening words of Section 40: "Any person who shall wilfully and falsely pretend to be. . . . Other statutes concerning other professions, such as those of a solicitor or a dentist, did not contain the words "wilfully and falsely." If Mr. Havers's contention that the title "doctor of medicine" could only be used by a registered person was right, it would be an offence for the Regius Professor of Medicine at one of our great universities, who might not have taken steps to be registered because he had no intention of practising, to describe himself as a doctor of medicine. Counsel had also submitted alternatively that the Act at least prevented a man from using the title unless he was qualified to be registered; but the Court could find no words in the Act to support that contention. A man could be registered only if he possessed certain qualifications; but if he used a title which would imply that he was registered, he would commit an offence if he were not in fact registered, however qualified he might be.

The full court had been convened particularly because the judgments in the earlier case of *Jutson v. Barrow* (1939) contained some dicta which appeared to conflict with earlier authorities which had not then been cited to the court. *Jutson's* case seemed to contain an absolute prohibition against the use of the description "doctor of medicine" by an unregistered person who had a genuine doctorate; but that case was distinguishable from the present one, as that practitioner had been medically unqualified besides being unregistered. The earlier cases before *Jutson v. Barrow* represented an unbroken line of authority from 1860 to 1899 to the effect that to commit an offence against Section 40 the defendant must have acted wilfully and falsely; that it was for the justices to decide whether he had done so; and, also, that he did not commit an offence if he honestly believed that he was within his rights in describing himself as he did. He must, of course, have a reasonable ground for his belief. The presence or absence of the "guilty mind" must be tested on ordinary principles and in the light of common sense.

Dr. Luftig had a genuine degree of doctor of medicine conferred by a foreign university. There was therefore no reason why he should not use that title, and the justices had been amply justified in finding that he did not use it wilfully and falsely. If Dr. Luftig described himself as "M.D. Berlin," then, clearly, on the authorities, he was entitled to do so and committed no offence; he was describing himself as what he was, and the addition of the word "Berlin" showed that he was not claiming to be possessed of one of the degrees mentioned in the Act, and, therefore, did not represent that he was registered. The real difficulty in the case was his use of the abbreviation "BLN." The authorities, however, obliged the court to hold that it was for the justices to decide whether, in so doing, he had acted falsely and wilfully, and they must be taken to have found that he did not so act.

The justices had further found that the description "M.D., BLN" did not imply that Dr. Luftig was registered. They might have decided that point the other way, and the court hoped that Dr. Luftig would not in future use that abbreviation. As there was some evidence on which the justices could find that Dr. Luftig had not acted wilfully or falsely, it followed that the appeal must be dismissed. The cases were in a

ANNOUNCING

*Aureomycin Hydrochloride**Lederle*

AUREOMYCIN HYDROCHLORIDE *Lederle* gives promise of being one of the most versatile antibiotics yet discovered. It is a potent antibiotic against many Gram-negative and Gram-positive organisms and against primary atypical pneumonia. AUREOMYCIN has been found useful in the control of infections caused by penicillin-resistant Gram-positive

cocci (especially staphylococci), and infections caused by coli-ærogenes bacteria. It is also highly specific against rickettsial infections. AUREOMYCIN has been used successfully against infections that have become resistant to penicillin, streptomycin, or sulphonamides, and in patients who exhibit severe and uncontrollable sensitivity to these latter drugs.

ADVANTAGES

Aureomycin exhibits the following advantages:—Essentially non-toxic (excepting allergy) . . . Unlikely to produce fastness in pathogenic organisms . . . Effective against many organisms previously insusceptible to chemo-therapy . . . Available in oral . . . and topical ophthalmic dosage forms.

CAPSULES: Vials of 16 capsules each containing 250 mg.
OPHTHALMIC: Vials of 25 mg. with dropper assembly; solution prepared by adding 5 cc. of distilled water.

**ORAL TREATMENT
FOR
SCHISTOSOMIASIS**

The discovery of 'Nilodin' is an important advance in the field of tropical medicine. The advantages of this new compound are such that it promises to become the drug of choice in the treatment of *Schistosoma hæmatobium* infestation.

- 90 per cent cure rate has been obtained*
- Hæmaturia ceases within 48 hours
- Course of treatment only 3 to 6 days
- Hospitalisation unnecessary
- Patients rapidly rendered non-infective
- Low toxicity
- Mass treatment of communities possible for the first time
- Effective orally

'Nilodin' is also effective to a lesser degree in the treatment of *S. mansoni* infestation. The compound is issued as 200 mgm. compressed, enteric-coated products, in bottles of 30 for individual treatment and 500 for mass treatment.

* Lancet, 1949, I, 344

'NILODIN'

1-DIETHYLAMINOETHYLAMINO-4-METHYLTHIOXANTHONE HYDROCHLORIDE

local antihistamine therapy with

'ANTHISAN' CREAM

trade mark

brand

ANTIHISTAMINIC The local application of 'Anthisan' Cream in the palliative treatment of skin manifestations of allergic and sensitization reactions is justified by its ability to neutralize the local effects of histamine by reducing oedema and relieving pruritus. The outstanding value of 'Anthisan' administered systemically is clearly established and, in appropriate cases, combined local and systemic treatment would appear to be the most promising method of obtaining speedy relief of symptoms.

ANTIPRURITIC The powerful local analgesic action of 'Anthisan' has suggested the local application of the Cream in various dermatoses characterized by intense pruritus, but not necessarily of allergic origin, and there is clinical confirmation of its value in such cases.

OUR MEDICAL INFORMATION DIVISION,

complete fog, and their Lordships thought the time had come when the position might be clarified by further legislation

Comment

The most difficult element in this important case was, of course, the absence of a clear prohibition against practice by an unregistered person, and the presence in its place, in Section 40, of the prohibition against the use of titles suggesting registration, with the requirement of proof of a guilty intent. The Court's decision settles a question which has been perplexing the profession and their legal advisers for the best part of a century, but it also legalizes the use of a variety of titles conferred by reputable foreign universities without specifying their source. What, also, is the position if a practitioner calls himself M.D. on the strength of a doctorate conferred by a Dominion university which is reputable enough but the medical qualifications of which the General Medical Council will not for the moment accept for registration, perhaps because the teaching or the examinations do not come up to the Council's standards? Will a court be asked to say that use of the title M.D. conferred during the period of the Council's disapproval infringes the Act although one conferred at another time is registrable?

It is probably too much to hope that Parliament will find time for the legislation suggested by the Court or that if it did it would restrict the practice of medicine to registered persons, but much trouble would be saved if it would remove the requirement "wilyfully and falsely" and make the use of an unregistered title unlawful irrespective of motive. Regius professors of medicine, presumably, could safely be left to look after themselves.

UNIVERSITY OF LEEDS

W. K. J. Walls, M.B., Ch.B., has been appointed Lecturer in Anatomy in the University

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council of the College held on June 9, with Lord Webb-Johnson, President, in the chair, the Honorary Medal of the College was presented to Mr. Arthur Sims, Professor F. Wood Jones, and Professor W. E. Gye.

A Certificate of Honourable Mention for his Jacksonian Essay was presented to Mr. C. G. Rob.

The following were co-opted to the Council for the year 1949-50, representing the branches of practice indicated in parentheses: Dr. H. Guy Dunn (General Practice), Mr. J. M. Wyatt (Gynaecology and Obstetrics), Mr. V. E. Negus (Oto-laryngology), Mr. A. D. Marston (Anaesthetics), Mr. J. H. Doggart (Ophthalmology), Professor R. V. Bradlaw (Dental Surgery), Mr. B. W. Wundeyer (Radiology).

Dr. H. D. Ross was appointed as Lecturer in Pathology in the College.

Diplomas of Fellowship were granted to the following successful candidates

C. W. F. Burnett, W. H. H. J. de W. de Wytt, R. D. Ewing, G. W. V. Greig, J. M. M. Drew, P. H. Hayes, H. W. Jackson, B. D. Sutter, E. N. Owen, Mary Savory, J. R. Hudson, G. R. Fisk, H. M. Jamison, J. P. Jackson, W. H. W. Jayne, E. P. Kempsey, R. T. Hinde, P. A. L. Roberts, M. Hershman, H. P. Jones, M. Bates, R. C. Bell, D. H. C. Harland, C. K. C. Smith, J. H. Peacock, P. B. Counsell, D. H. Teasdale, J. Wilks, T. J. Schofield, T. O. Candler, J. H. L. Ferguson, T. G. Harvey, G. C. Lloyd Roberts, H. O. Thomas, H. Davis, M. P. Pick, H. Hassall, T. B. Smith, C. H. Barnett, N. G. McGure, J. L. Wakeham, R. E. Connor, M. R. Williams, R. D. de Vere, D. H. Woodhead, C. H. de Boer,

W. H. Lonsdale, F. W. P. Dixon, W. Herschell, W. G. Schulze, D. J. Waterston, T. D. Kelly, A. P. Sandrasagra, J. R. Frylinx, K. C. McKeown, A. Y. Mason, J. E. Buck, P. K. Duraiswami, F. B. Korkus, W. R. McKeown, J. A. B. Thomas, J. D. Hallissy, K. Harrison, J. R. Magarey, D. M. Morrissey, C. J. Rustomey, G. R. Yarwood, W. P. Carwell, B. M. Hay, F. L. Herbert, J. D. Sidey, S. C. F. Stephenson, F. R. Zadik, H. K. Bouma, H. L. Brunow, T. C. H. Davies, K. N. Kashyap, A. I. Lichter, G. C. McKee, N. S. Rao, E. A. Turner, A. G. A. Albers, A. Glass, N. C. Newton, H. I. Rees, C. R. E. Stephens, C. Balakrishnan, S. de C. Barclay, G. G. Ferguson, J. B. Foster, N. A. Fowler, H. W. Gosland, D. Mack, Hamilton, L. A. Jacobs, E. L. H. Jones, H. H. Mirza, D. W. H. Ruddick, W. A. Wilson, G. Y. Akrawi, W. Burnett, O. O. Cowpe, I. D. Henderson, E. R. Leclutier, W. J. S. Melvin, A. F. Robinson, F. Robinson, P. J. M. van Merit, D. J. Wurth, D. Yassa, I. F. Barwell-Clarke, N. K. Connolly, M. Friedman, J. C. Frew, N. S. Hooton, S. Konar, J. M. Langham, D. M. McG. Portley, J. H. Saunders, Barbara F. Smith, J. R. Stanley, J. K. Watt, A. R. Ancombe, P. F. Boreham, R. Brearley, J. E. Crichtley, R. B. Lynn, S. Sen.

Diplomas of Membership were granted to Eleanor H. Barrington, Thelma W. Dafforn, and S. N. Mathur.

Dr. C. W. Freeman (U.S.A.), Colonel J. L. Bernier (U.S.A.), Dr. R. Ahmed (Calcutta), Dr. N. N. Bery (Delhi), Dr. V. M. Desai (Bombay), and Dr. H. P. Mooglanonkar (Bombay) were elected Fellows in Dental Surgery.

A Diploma in Tropical Medicine and Hygiene was granted jointly with the Royal College of Physicians of London to Y. G. Abdelai.

Diplomas in Medical Radio-diagnosis, in Medical Radiotherapy, and in Anaesthetics were granted jointly with the Royal College of Physicians of London as follows

DIPLOMA IN MEDICAL RADIO-DIAGNOSIS—D. H. Bodger, P. Cliff, J. F. Donerty, P. K. D. Edmunds, A. Giordano, T. Griffiths, P. K. Haldar, D. J. Harries, B. B. Harrison, Hung-Chun Ho, G. T. Holroyd, G. A. MacDonald, J. P. MacLaughlin, H. F. March, T. L. C. Pratt, S. P. Robson, F. G. M. Ross, J. Rubin, Jean V. Sheach, J. A. Shiers, G. M. Sinclair, D. S. Singh, C. C. Smith, R. S. Smith, P. H. D. Stone, Z. L. Szur, R. J. S. Walker, A. S. Whitehead, F. B. Wright.

DIPLOMA IN MEDICAL RADIO-THERAPY—J. G. D. Bell, W. H. Bond, I. F. J. Churchill Davidson, L. Cohen, W. G. Green, S. Kramer, Marjorie S. Mullin, R. F. Parfitt, J.

DIPLOMA IN ANAESTHETICS—D. C. Adamson, T. D. Ap Ivor, Agnes W. Baker, D. K. Ballingall, D. Beaton, F. W. Chippindale, H. A. Condon, Margaret R. Connolly, Elizabeth S. N. Fenton, E. N. S. Fry, K. B. Glynn, J. J. Hargadon, C. B. Holland, C. D. T. James, R. D. Lewis, O. L. Lewis, S. Lipton, W. G. G. Loya, L. E. McDonnell, W. G. McEwen, B. H. McGurk, E. S. Macchell, H. G. Middleton, B. G. P. Oakenfull, N. P. Read, M. E. Samrah, R. G. Sykes, J. E. Tees, J. G. Warnock, H. Y. Wishart.

The following hospitals were recognized under paragraph 23 of the F.R.C.S. regulations: Bromley Hospital (Senior and junior house-surgeon), Cirencester Memorial Hospital (Senior house-surgeon), (until June, 1950), Farnborough Hospital (Registrar to ear, nose, and throat unit), Central Middlesex Hospital (Surgical registrar oto-rhino laryngology).

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

The following have been admitted as Fellows of the College: Honor. M. Purser, J. A. O'Sullivan, S. P. Dundon, B. G. Alton, B. Mayne.

The following have been admitted as Members of the College: W. L. Burrows, C. P. Dempsey, R. S. Garewal, J. B. Lyons, M. A. Mayekodunmi, B. E. Swain, J. M. Taylor, E. L. Wilson, M. B. Conlon (*in absentia*).

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

At a meeting of the Council of the College held on May 23, with the President, Sir William Gilharr, in the chair, the following were elected to Council to fill vacancies caused by retirement, statutory and otherwise. As representatives of the Fellows: Professor O'Donel Thornley, D. Browne (Dublin), Mr. George Frederick Gibberd (London), Professor Hilda Nora Lloyd (Birmingham), Mr. John Eric Stacey (Sheffield). As representatives of the Members: Mr. Gavin Boyd (Belfast), Leslie Bonthron Patrick (Sheffield).

The following were admitted to Fellowship of the College: Doris C. Bates, R. B. Charlton, K. M. K. Duff, M. D. A. Evans, J. D. S. Flew, B. Gilbert, J. W. Johnstone, W. I. C. Morris, Margaret M. Nolan, C. K. Vartan, W. Waddell, R. G. Worcester.

The following were admitted to Membership of the College: G. McG. Barr, A. C. Barthels, D. W. Bentuck, B. Bhattacharya, D. K. Black, Kathleen M. Bower, Muriel Brighton, C. H. Brown, J. M. Buchanan, D. P. Cocks, H. J. A. Conte-Mendoza, E. Cope, S. E. Craig, F. A. L. da Cunha, F. B. Davidson, J. Dei, F. Denny, N. S. Devi, C. J. Dewhurst, Kathleen A. Dru Drury, J. G. Dumoulin, J. M. Duncan, L. T. El Badri, B. H. Ellis, H. R. England, I. B. Farris, B. J. Frankenberg, J. S. Fraser, W. K. Frewen, H. G. Furnell, L. W. Gall, G. B. Gibson, L. S. Glass, Cecile Greig, G. T. H. Harris, E. I. Holloway, C. G. Irwin, W. H. Laird, R. G. Law, Silvia C. Lewin, Ethna W. Little, L. E. Loumer, R. L. Lunt, J. G. McCarroll, H. A. McCredie, J. A. McGhie, J. F. McInerney, R. M. McIntosh, I. D. Macintyre, A. A. McKirdy, A. T. McNeil, D. S. Mathews, G. Mitchell, J. E. E. Morgan, N. F. Morris, N. Noble, A. F. Pearson, H. E. Pellew, H. K. Porter, D. A. Ranasinghe, B. C. M. Reed, J. S. Reid, W. A. Robson, E. S. Rogers, J. K. Russell, H. Sayeed, C. R. Slumming, D. F. Smith, R. B. C. Stevenson, A. S. Subramani, J. Suchet, B. M. Sutherland, Eleanor Tennant, Mary E. Tighe, Mary U. Wilkin, E. O. Williams, E. G. Zacks.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended June 4.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland (d) Eire. (e) Northern Ireland

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county) (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1949					1948 (Corresponding Week)

* Measles and whooping cough are not notifiable in Scotland, and the returns are therefore an approximation only

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland

§ The number of deaths from poliomyelitis and poliomyelitis for England and Wales, London (administrative county), are combined.

¶ Includes puerperal fever for England and Wales, Eire, and Northern Ireland.

EPIDEMIOLOGICAL NOTES

Typhoid Fever at Fulham

Five cases of typhoid fever are now known to have occurred in Fulham M.B., in children between the ages of 4 and 14. The dates of onset were between May 29 and June 5. One patient, a girl aged 10, died. A few suspects admitted to hospital at about the same time have now proved to be free from infection. All five children were living close to each other in the south-east part of the borough and all have been shown to be infected with the same organism, Vi-phage Type D1. The usual inquiries have failed to bring to light a common aliment, although all are known to have eaten ice-cream from itinerant vendors about the presumed date of infection.

Discussion of Table

In England and Wales increases were reported in the notifications of measles 190 and dysentery 14. There was a decrease of 433 in the notifications of whooping-cough.

The largest increases in the incidence of measles were London 130 and Middlesex 98; the largest decreases were Kent 247, Yorkshire West Riding 116, and Derbyshire 92. The only notable change in the returns for scarlet fever was a decrease of 29 in Yorkshire West Riding. There was very little change in the notifications of diphtheria; a decrease of 5 in London was the largest variation. The chief feature of the notifications of whooping-cough was a decrease of 94 in Warwickshire.

Notifications of dysentery rose from 16 to 67 in Lancashire. The chief outbreaks in this county were Oldham C.B. 39, Liverpool C.B. 11, and Chadderton U.D. 11. A large outbreak of food poisoning with 161 cases was notified in Yorkshire West Riding, Bradford C.B.

In Scotland there were decreases in the notifications of measles 140, whooping-cough 34, and scarlet fever 15. There were increases in the incidence of diphtheria 17 and acute primary pneumonia 15. In the city of Glasgow the notifications of diphtheria and dysentery respectively were 12 and 10 above the totals for the preceding week.

In Eire the notifications of whooping-cough increased by 50, and the notifications of diarrhoea and enteritis decreased by 9. The rise in the incidence of whooping-cough was due to small outbreaks in the rural districts, notably Dublin, Cill Droichid No. 2 R.D., 21.

In Northern Ireland the largest variation in the returns of infectious diseases was a rise of 11 in the notifications of scarlet fever.

Week Ending June 11

Notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,090, whooping-cough 1,806, diphtheria 81, measles 9,249, acute pneumonia 416, cerebrospinal fever 28, acute poliomyelitis 17, dysentery 53, paratyphoid 24, and typhoid 9.

Medical News

Visitors to Colombia

Mr. Ronald W. Raven and Dr. Laurence H. Morris have recently returned from Colombia, where they spent five weeks in the university teaching hospitals of Bogota, Medellin, and Cartagena. Mr. Raven delivered a course of lectures on the surgical treatment of cancer and performed operations for this disease. Dr. Morris gave lectures and demonstrations on anaesthesia. This is the first occasion on which a British surgical mission has visited Colombia; the invitation was given by the National University. Mr. Raven was elected honorary professor of the National University. The honour was conferred at a special meeting of the Academic Council of the university at which the British Ambassador was present. The honorary professorship has been given on seven previous occasions, but not before to a British subject.

Analysis of Public Health Nursing

The Nuffield Provincial Hospitals Trust, which has been conducting a detailed job analysis of the work of hospital nurses, will conduct a similar investigation in the field of public health nursing. This includes health visitors, home nurses, school nurses, tuberculosis visitors and nurses, and clinic nurses. It does not include midwives. A pilot survey will be carried out in six areas in England and Wales and two in Scotland (in Dundee and Lanarkshire) to test the method of analysis, after which the survey will be extended to a large number of areas throughout the country.

New Journal for Industrial Nurses

A new quarterly journal entitled *Journal for Industrial Nurses* comes from the Nuffield Department of Occupational Health at the University of Manchester. It will help nurses working in factories and industrial areas to understand the hazards peculiar to industrial life. The first number includes an article on "The Nurse in Her Treatment-room," by Professor R. E. Lane, and an account of "Health Problems Incidental to Pottery Manufacture in North Staffordshire," by Dr. Andrew Meiklejohn. Dr. R. S. F. Schilling discusses "A University Department of Occupational Health."

Medical Visitor from Greece

Professor Charles Alexandridis, professor of clinical medicine in the University of Salonika, arrived in London on June 14 under the auspices of the British Council to observe progress in general clinical medicine in Britain and meet British specialists in tropical diseases and diseases of the heart and blood. Professor Alexandridis is a past President of the Medical Society of Salonika and a Fellow of the Royal Society of Tropical Medicine and Hygiene.

Anti-measles Serum

Doctors wanting to obtain anti-measles serum should not prescribe it on Form EC 10 but should apply to the nearest public health laboratory. The address of the laboratory if not known, can be obtained from the medical officer of health.

Holidays for Chemists

The Minister of Health considers that, where a chemist wants to take a holiday but is unable to provide a deputy in his absence, he should be able to go for a week or two during the summer season if a rota can be arranged with neighbouring chemists.

Council of the R.C.V.S.

The council of the Royal College of Veterinary Surgeons has been reconstituted in accordance with the Veterinary Surgeons Act, 1948. Professor T. Dalling, Chief Veterinary Officer at the Ministry of Agriculture, has been elected president of the College for 1949-50. The Act provides that there shall be 20 elected members who are members of the Royal College and who are elected by their fellow members outside the Republic of Ireland. It also provides for four people to be appointed by the Privy Council and two for each university in the United Kingdom which has a registrable veterinary degree, one of these two from each university must be a member of the Royal College. The Act also lays down transitional provisions pending the establishment of a registrable veterinary degree in the various universities.

Wills

Sir Edmund Ivens Spriggs, of Ruthin, Denbighshire, left £18,273. Dr. Andrew Messer, of Lemington, Northumberland, left £5,610. Dr. Eric St. George Gilmore, of Chorlton cum Hardy, Manchester, £3,082. Dr. Robert Everard Whitting, formerly of Oxted, Surrey, £6,975, and Dr. Alfred Eugene Martin, of Boreham Wood, Herts, £27,223.

COMING EVENTS**Alexander Simpson-Smith Lecture**

The Alexander Simpson-Smith Lecture for 1949 will be delivered under the auspices of the Institute of Child Health of the University of London by Professor Gordon Murray, Associate Professor of Surgery in the University of Toronto, at the Hospital for Sick Children, Great Ormond Street, London, W.C., on Monday, July 11, at 5 p.m., with Lord Webb-Johnson, P.R.C.S., in the chair. His subject is "The Artificial Kidney." Admission is by ticket only, obtainable from the Dean of the Institute of Child Health at the hospital.

Prosser White Oration

The Prosser White Annual Oration of the St. John's Hospital Dermatological Society will be given at the Royal Society of Medicine (1, Wimpole Street, London, W.), on Wednesday, July 6, at 4.30 p.m., by Professor Marion B. Sulzberger, Professor of Dermatology and Syphilology of the New York Skin and Cancer Unit. His subject is "Allergy: A Dermatologist's Reminiscences and Speculations."

Royal Institute of Public Health and Hygiene

The Harben Medal for "eminent services rendered to the public health" will be presented to Lord Boyd Orr, F.R.S., and the Smith Award "to one recognized as having done the most noteworthy work in the discharge of his official duties" to Dr. M. T. Morgan, medical officer of health, Port of London Health Authority, at a meeting at the Institute (28, Portland Place, London, W.) on Thursday, July 21, at 3 p.m.

Urological Surgeons

The British Association of Urological Surgeons will hold its fifth annual meeting on June 30-July 3.

City and Hospitals Charity Contest

The City and Hospitals Charity Athletic Contest for the *Financial Times* Challenge Shield will be held at the University of London Sports Ground, Mootspur Park, Surrey, on July 9. The admission fee is 1s. 6d. The proceeds will be devoted to charity.

Clinical Pathologists

The Association of Clinical Pathologists will hold its 42nd Scientific Meeting at the Department of Pathology, University College, Cork, on July 22 and 23.

Birmingham Region Consultants

A general meeting of all consultants and specialists in the Birmingham Region will take place on Saturday, June 25, at 2.15 p.m. at Nuffield House, Queen Elizabeth Hospital, Birmingham.

Commemoration Service

A special service has been arranged by the Indian Church Aid Association to be held at St. Margaret's, Westminster, on July 7 at 11.30 a.m. as a solemn act of commemoration and thanksgiving for the lives and work of many generations of British men and women who served in India in the various Indian Services, in the British and Indian Armies, in the work of the Church and missions, and in the field of trade and industry. Further information can be obtained from the secretary, Indian Church Aid Association, 5, Victoria Street, London, S.W. 1.

N.A.P.T. Jubilee

Jubilee celebrations to be held by the National Association for the Prevention of Tuberculosis will include a Commonwealth and Empire Health and Tuberculosis Conference at the Central Hall, Westminster, on July 5-8, 1949.

SOCIETIES AND LECTURES**Tuesday**

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—June 28, 5 p.m., "Background of Occupational Dermatoses" by Dr. R. M. B. MacKenna.

INSTITUTE OF UROLOGY—At St. Paul's Hospital, Endell Street, London, W.C., June 28, 11 a.m., "Granuloma Venereum and Lymphogranuloma Inguinale," by Dr. W. N. Mascall.

Wednesday

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—June 29, 5 p.m., "Systemic Mycological Infections," by Dr. Clara Warren.

INSTITUTE OF UROLOGY—At St. Paul's Hospital, Endell Street, London, W.C., June 29, (1) 11 a.m., "Reiter's Syndrome" by Dr. A. H. Harkness, (2) 5 p.m., "A Survey of the Different Methods of Treatment available in Enlargement of the Prostate" by Mr. R. Oger Ward.

Thursday

CLINICAL SOCIETY OF THE ROYAL FREE HOSPITAL, Gray's Inn Road, London, W.C.—June 30, 5.15 p.m., "The Open Wound in Surgery and its Function," by Mr. Peter Essex-Lopresti. Visitors welcomed.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—June 30, 5 p.m., "Acne" by Dr. H. Corsi.

INSTITUTE OF UROLOGY—At St. Paul's Hospital, Endell Street, London, W.C., June 30, (1) 11 a.m., "Condylomata Acuminata" by Dr. A. H. Harkness, (2) 5 p.m., "Transvesical Operations on the Prostate," by Mr. W. K. Irwin.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE, Keppel Street, W.C.—June 30, 3 p.m. Films "The African Schistosomiasis" (for instruction of medical profession) and "Still Waters" (for public education).

LONDON UNIVERSITY—At Institute of Neurology, National Hospital, Queen Square, London, W.C.—June 30, 5 p.m., "Rathke's Pouch Tumours" by Professor Geoffrey Jefferson, F.R.S.

ROYAL SOCIETY, Burlington House, Piccadilly, London, W.—June 30, 4.30 p.m., "The Rhythmic Action and Respiration of Nerve Cells." Croonian Lecture by Professor D. W. Bronk, Ph.D. (Philadelphia).

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—June 30, 4.30 p.m., "Neurology," lecture demonstration by Dr. D. J. Williams.

Friday

NORTH OF ENGLAND SOCIETY OF ANAESTHETISTS AND NEWCASTLE-UPON-TYNE OBSTETRICAL AND GYNAECOLOGICAL SOCIETY—At Royal Victoria Infirmary, Newcastle-upon-Tyne, July 1, 7.30 p.m. "Analgesia for Obstetrics" by Dr. Robert A. Hingson (Baltimore).

APPOINTMENTS

COYNE, W. J., M.D., F.R.C.P.I., D.P.H., D.P.M., Governor, Central Criminal Asylum, Dundrum, Co. Dublin.

SMITH, J. MACLEAN, M.B., F.R.F.P.S., Fellow in the Department of Medicine, Johns Hopkins Hospital, Baltimore, 5, Maryland, U.S.A.

THOMAS, H. ORISHOLOMI, M.B., F.R.C.S., Lecturer, Department of Surgery, University College, Ibadan, Nigeria.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Ackner.—On June 11, 1949, at Bromley, Kent, to Jean (née Marley), wife of Dr. Brian Ackner, a son

Clynton Reed.—On May 29, 1949, at Military Families Hospital, Moascar, M.E.L.F., to Jean Neilson (née Roy), wife of Lieutenant Colonel J. Clynton Reed, O.B.E., R.A.M.C., a son

Cox.—On June 9, 1949, at 29 British Military Hospital, Hanover, to Dr. Irene, wife of Captain John Cox, R.A.M.C., a son—Jonathan Michael.

Imay.—On June 3, 1949, in London, to Solange (née de la Motte), wife of Dr. D. G. Imay, a daughter

Laurance.—On June 9, 1949, at Weekley Rise, Kettering, to Audrey (née Kidner), the wife of Dr. Bernard M. Laurance, a son.

Rainer.—On June 10, 1949, at Bristol, to Iris, wife of E. H. Rainer, F.R.C.S., a second daughter—Madeleine Dorothy

Tallack.—On June 4, 1949, at the Government Hospital, Weic, Pemba, Zanzibar, to Joyce, wife of Dr. R. J. K. Tallack, Colonial Medical Service, a daughter

MARRIAGES

Milo-Turner.—On June 10, 1949, at St. Bartholomew's Church, Penn., Gilbert Milo-Turner, M.B., Ch.B., D.R.C.O.G., Tamworth, Staffs, to Felicity Mary Burne, S.R.N., "Wayford" Coalway Avenue, Wolverhampton.

Richards-Tighe.—On June 4, 1949, at St. Paul's Church, Sketty, Swansea, Denis George Blackwood Richards, M.R.C.P., to Mary Elizabeth Tighe, M.R.C.O.G.

DEATHS

Elliott.—On June 10, 1949, Charles Norton Gavin Elliott, L.R.C.P.S. Ed., L.R.I.P.S. Glas., formerly of Old Portsmouth, and of Histon, Denmead, Hants

Johnston.—On June 4, 1949, at Kendal, George Ainslie Johnston, M.D., F.R.C.S.I., of Old House, Ambleside, Westmorland

Macaulay.—On June 6, 1949, at Hawthornbank, Selkirk, Scotland, Thomas Symington Macaulay, M.D., F.R.F.P.S., D.T.M.&H., aged 67.

MacDonald.—On June 5, 1949, at 20, Brislington Hill, Bristol, William Forbes MacDonald, M.D., C.M.

McGrath.—On June 2, 1949, at 230, Kingston Road, Staines, Middlesex, John Joseph McGrath, M.D., D.P.H., formerly of Surbiton, Surrey.

Nicholls.—On June 3, 1949, at Clairfaye, Seaton, Devon, Thomas Burtonshaw Nicholls, M.B., Ch.B., Lieutenant-Colonel, R.A.M.C. (ret.).

Routh.—On June 6, 1949, at 141, Durlough Road, Bridgwater, Somerset, Randolph Henry Felix Routh, M.R.C.S., L.R.C.P., aged 87.

Salkeld.—On June 7, 1949, at 36, Dean Park Road, Bournemouth, Charles Salkeld, M.B., B.S., aged 81.

Sharp.—On June 6, 1949, suddenly, on Okhampton golf course, Christopher James Lewen Sharp, M.C., M.B., B.Ch.

Slattery.—On June 10, 1949, at "The Shanty," Totnes, Devon, James Beary Slattery, M.D.

Southey.—On May 30, 1949, William George Southey, M.B., B.S., D.P.H., of 44, Wellowgate, Grimsby, Lincs

The need for the greatest possible economy in the running of the hospital services was emphasized by the Rt. Hon. Arthur Woodburn, M.P., Secretary of State for Scotland, when he met the chairmen of the five Scottish regional hospital boards and of the boards of management in the four Northern and Eastern Regions in St. Andrew's House, Edinburgh, recently. Mr. Woodburn added, however, that the Government had no intention of cutting down on essential services—such as the provision of beds and nurses. If a thing was absolutely necessary it should be provided. He had no doubt that hospitals were already being run economically and that charges of gross extravagance were unjustified. People who thought, perhaps naturally, that the cost of hospital service was enormous forgot that, apart from the recent necessary increase in salaries, the vast bulk of hospital expenditure was not new. It was not his intention to issue any specific instructions on how economies were to be effected. The boards of management, as the people on the spot, would know best what developments could be postponed and what services spared. But, especially in view of the recent increases in nurses' salaries, he had to ask the boards to take a second look at their services and see if anything could be cut down. Real economies were more likely to come from small savings here and there throughout the Service than from any one spectacular cut. He thanked the boards for the excellent work they had done. It was a measure of their success that, despite the natural tendency to criticize public bodies, the only point of serious criticism about the hospital service had been its popularity and hence its cost. In the course of general discussion it was said that while relationships were good there was not enough contact between regional hospital boards and boards of management. A plea for more round-the-table conferences was advanced. Various chairmen argued that everything possible was being done to secure economies, but a great deal of lee-way had to be made up, particularly in view of the neglect during the war years.

Penicillin Enhancement Factor

Q.—My clinical experience has been that the new crystalline pure penicillin is not so effective as the sodium salt which preceded it. Is this the general view and, if so, why?

A.—There are several different penicillins with a common nucleus but with different side-chains. Up to 1944 most of that produced commercially was in the form of penicillin G; thereafter purer compounds appeared which contained a larger proportion of the less active penicillin K. The amorphous penicillin seems to contain impurities which enhance its effect *in vitro* and in animal experiments. These substances are heat-stable, and are together known as the "enhancement factor"; they are, of course, absent from crystalline penicillin G. Many clinicians have entertained suspicions similar to those of the questioner, but careful clinical trials have not shown that crystalline penicillin combined with enhancement factor is more effective than crystalline penicillin alone.

Cremor Sulphanilamidi et Sulphathiazoli, N.W.F.

Q.—The National [War] Formulary, 1947, contained a valuable antiseptic cream—cremor sulphanilamidi et sulphathiazoli. Is there any valid reason for its omission from the National Formulary, 1949? How can sulphanilamide and sulphathiazole cream be prescribed in future unless the prescription is written in full? Incidentally, what justification is there for the new cremor proflavinae? There seems to be more than a suspicion that oily preparations of proflavine are useless as bacteriostatic preparations.

A.—The National Formulary contains no sulphonamide cream because the balance of evidence is unfavourable to the local use of this group of drugs. There is, indeed, little satisfactory evidence that they are effective, but definite evidence that they may give rise to toxic reactions. The current view in the U.S.A. is summarized in the statement in *New and Non-official Remedies*, 1948:

"Experience gained in World War II seems to indicate that the use of crystalline sulphonamides and of sulphonamide ointments, creams, lotions, etc., as topical agents was not very successful in the management of wound infection or in treatment of infections of the skin or mucous membrane. The routine use of sulphonamides as topical applications in wounds, burns, and in superficial infections is therefore to be discouraged."

Sulphonamides locally applied may be harmful, since they may produce sensitization reactions in the skin if they are used for more than a few days. Once this has occurred it may prove impossible to give the same or even a different sulphonamide by mouth or locally without inducing a generalized eruption. Sulphathiazole is particularly liable to give rise to this form of sensitization.

[The preparation cremor proflavinae replaces the emulsio acriflavinae, B.P.C., which is popular mainly because it does not cause dressings to adhere to abraded surfaces. Garrod and Keynes (*British Medical Journal*, 1937, 2, 1286) state of the emulsio acriflavinae, B.P.C., that "it has no demonstrable action whatever." The cremor proflavinae, N.F., though it contains the less toxic substance proflavine, is nevertheless still an oil-in-water emulsion, and, as the question suggests, the active drug will tend to remain in solution in the oily phase where it cannot exert much antiseptic activity. Wood (*Pharm. J.*, 1939, 1, 327) has pointed out that emulsions of the water-in-oil type have far greater antiseptic activity in laboratory tests, and describes methods for making such preparations. The cremor aminacrinae, N.F., could be used as an application to wounds, ulcers, and burns, though it is intended primarily as an obstetric cream for application to the hands. The aminacrine is non-staining and is presented in a glycerin-jelly base.]

EXAMEN—LIVER EXTRACT IS STANDARDISED

IN TERMS OF THE ANTI-ANAEMIC FACTOR (vitamin B₁₂)

The isolation in Glaxo Laboratories of the pure crystalline anti-anaemic factor has provided a standard by which the potency of liver extracts can be precisely expressed. Examen, in addition to receiving clinical trial on each batch, is now standardised microbiologically. Its potency is —*

12 MICROGRAMS OF ANTI-ANAEMIC FACTOR (B₁₂) IN ONE CC.

the amount ample to give optimum response during fourteen days in pernicious anaemia in relapse.

1cc. ampoules (boxes of 3 & 6) 5cc. vials (boxes 1 & 5)

**Nature* (1948) 162, 144

GLAXO LABORATORIES LTD., Greenford, Middlesex, England

A New Curarising Agent

The curarising action of decamethonium iodide (bistrimethylammonium decane di-iodide or C 10) was reported in *Nature*, 1948, 162, 810.

On the basis of tests on laboratory animals it was demonstrated that this compound has a powerful action in blocking transmission at neuromuscular junctions. This action spares the respiration and is not associated with a marked liberation of histamine.

Preliminary reports of the action of this compound on human subjects, published in the *Lancet*, 1949, 1, 22, indicated the clinical potentialities of this synthetic neuromuscular blocking agent for producing muscular relaxation during anaesthesia or convulsive therapy.

This compound is now available under the name EULISSIN and is supplied in ampoules containing 5 mg. in 2.5 c.c. in boxes of 6, 12 and 100 ampoules.

Eulissin is not antagonized by neostigmine but an antidote, when needed, is available in ANTILUSIN (pentamethonium iodide or C 5).

EULISSIN

TRADE MARK

Sterile Solution of decamethonium iodide.

Further particulars available on application to.

ALLER & HANBURY LTD. LONDON E2

Stimulant action in emergency

Anacardone (Injection of Nikethamide B.D.H.) should be at hand in the surgery and in the doctor's bag ready for immediate use.

Nikethamide B.D.H. exerts a rapid stimulatory effect on the respiratory and vasomotor centres thus raising the depth and rate of respiration and improving the blood supply to the heart in acute collapse.

Anacardone is available in ampoules as Injection of Nikethamide B.P. and as a 25 per cent. solution, flavoured, for oral administration.

Varicose Ulcer of Long Duration Healed by Elastic Compression Therapy

CASE HISTORY: E. S. Housewife aged 72 years. Varicose ulcer of 27 years duration upon antero-lateral aspect of lower 1/3 left leg. (Fig. 1.)

TREATMENT: June 21st 1948: Area of ulcer 56 sq. cms. Elastoplast applied as follows:—

No dressing to ulcer. Stirrup from head of fibula along lateral side of leg, under sole and up medial aspect of leg to level of tibial tubercle. Long strip from tibial tubercle along anterior surface to base of toes. Elastoplast applied as continuous circular turns from base of toes to tibial tubercle enclosing heel, each turn overlapping the preceding one by 2/3 of its width. (Fig. 2). One and a half bandages were required and were applied as tightly as possible by hand. Patient instructed to perform normal household duties.

PROGRESS: June 28th, 1948: Area 56 sq. cms. Ulcer base clean. Odour far less objectionable. Elastoplast reapplied as before. Patient seen at fortnightly intervals. Area of ulcer calculated at each visit. Elastoplast re-applied as before.

July 21st, 1948: Area 30 sq. cms. Odourless.

September 1st, 1948: Area 7 sq. cms.

November 3rd, 1948: Area 1/4 sq. cm.

November 24th, 1948: Ulcer healed. Total duration of treatment 22 weeks. (Fig. 3).

FURTHER TREATMENT: December, 1948: Elastic stocking supplied.

February, 1949: Juxtafemoral ligation and retrograde injection of left internal saphenous vein.

The details and illustrations above are of an actual case. T. J. Smith & Nephew Ltd., of Hull, manufacturers of Elastoplast, publish this instance—typical of many in which their products have been used with success.

ENSIGN X-RAY FILM

STANDARD

The fine definition which this film is capable of giving, and its ability to batch, consistency, make it highly suitable for Radiography of the chest regions. Radiographs on "Standard" X-Ray film are remarkable for their clearness and complete absence of fog.

RADOS (NON SCREEN)

— a fast film widely recognised for the fully graduated image which it gives. Greatly preferred for all orthopaedic work where perfect bone detail is essential. Its suitability for all types of equipment is assured by a really exceptional latitude in exposure

FOR MAXIMUM DIAGNOSTIC VALUE

BAYER

The Steadying Hand of 'PROMINAL' Trade Mark In Epilepsy

Of first importance to the epileptic is a drug which will enable the patient to live normally and usefully.

Under 'Prominal' therapy, fits are effectively suppressed, while the patient remains alert and able to carry on with his usual occupation.

The dose varies between 1½ and 9 grains daily, and is adjusted to the individual need. When 'Prominal' is used to replace 'Luminal,' the change-over should be gradual.

Available in tablets of ½, 1 and 3 grains.

Medical literature will be gladly sent upon request

'PROMINAL' may be obtained under the name of 'PROMITONE' overseas

BAYER PRODUCTS LIMITED
AFRICA HOUSE, KINGSWAY, W.C.2. HOL-8730

In justification of the admission of the cremor proflavinae to the *National Formulary* it should be pointed out that the objections to it are based entirely on *in vitro* bacteriological studies. Many dermatologists are convinced of its activity as an antiseptic in clinical practice, and its inclusion in the *Formulary* was decided on only after approval by a committee of dermatologists.

Diphtheria Immunization

Q.—What boosting dose of diphtheria immunizing material should be given to boys entering a boarding-school at the age of 12 to 14? Please discuss the following groups: (a) those immunized in infancy but not since; (b) those immunized in infancy and given a boosting dose at 5 years but none since; (c) those given only primary immunization at the age of 5 to 7 years. What material is recommended?

A.—Boys of 12 to 14 entering a boarding-school with a variety of histories of previous artificial immunizations, to which must be added some degree of latent immunization, present a problem somewhat similar to that of student nurses entering hospital. It is necessary to find out what proportion of them are immune, irrespective of previous history, and this can best be done by Schick-testing all new entrants. Those who are Schick-positive should be given one dose of diphtheria prophylactic—for example, 0.2 ml. A.P.T.—if they have been previously immunized, and two doses of 0.3 ml. A.P.T., at a month's interval, if they have not; those who are Schick-negative may be left alone or given a single injection of 0.2 ml. T.A.F.

Difficulty arises in the case of boys in whom a pseudo-reaction with the control material occurs. They will usually give a severe local and sometimes constitutional reaction to any diphtheria prophylactic, and the best course is to leave them alone and to carry out another Schick test three to six months later. Of the three groups mentioned in the question, most of the boys who were immunized in infancy and had a booster dose at 5 years should be Schick-negative, since the booster dose has a decidedly stimulating effect on antibody production. Some authorities will recommend a booster dose for all three groups, irrespective of the Schick reaction; but, if this were done, some severe reactions, which would no doubt create a bad impression among the other boys and the parents, may be expected. T.A.F. is probably the prophylactic of choice at present for a booster dose, and a small amount—for example, 0.2 ml.—will suffice.

Senility and Testamentary Capacity

Q.—A man of 80 died of senility in a home for the aged, where he had been resident for a year. During this time he made a will, legally correct and duly witnessed by a solicitor and a male nurse, leaving the residue of his property to his son and only small legacies to his three daughters. The latter feel that this was not their father's intention, and that they should contest the will on the grounds of the testator's senility. What is their position?

A.—The will in this case could be successfully challenged only if the daughters can satisfy the court that their father, at the time he made the will, was unable, owing to senility, to understand what he was doing. The court would probably not accept the general proposition that senility is always progressive and does not admit of "lucid intervals"; on the contrary, it is common knowledge that the mental powers of senile patients, at least in the early stages of the disorder, may fluctuate considerably. It is recorded of Sir William Blizard, F.R.S. (*Brit. J. Surg.*, July, 1920, p. 4), that he died at the age of 92 of senile decay, but that he continued on the surgical staff of the London Hospital until the age of 91, and was actually engaged in his ordinary duties as an examiner at the Royal College of Surgeons only a week before his death. The court would presume that the testator had sound testamentary capacity unless the contrary is proved by evidence. The daughters should seek such evidence, which might be provided by the doctor in charge of the home in which their father was living at the time he made the will. The particular points on which the doctor should express an opinion are: whether the testator understood that all his children had a reasonable expectation of a fair share of the estate, and whether he had any reasonable grounds for leaving the bulk of it to the son to the exclusion of the daughters.

It was held in *Cartwright v. Cartwright* (1793, 1 Phill. 90; quoted with commentary by Kitchin, *Legal Problems in Medical Practice*, 1936, p. 143) that where the making of a will appeared to be "a rational act rationally done" the will should be upheld, even though the testator had manifested undoubted signs of mental disorder before and after making it. Any evidence relating to the testator's state of mind at the time he made the will should be considered, including that of the solicitor and the male nurse who witnessed the document; inquiry should also be made about whether the testator suffered from any delusions relating to the daughters—for instance, whether, without reasonable cause, he thought them unfit to inherit; or falsely believed them to be already properly provided for.

Protein Shock Therapy

Q.—What is the usual intravenous dose of T.A.B. for protein shock therapy? What is the usual period between doses and, regarding anaphylactic reaction, what is the longest period observed between widely separated doses when the phenomenon has little chance of developing? For instance, if a patient received this form of T.A.B. a year ago, and now an intradermal skin test produces a marked reaction, does this contraindicate a repetition of intravenous therapy?

A.—The usual dose of T.A.B. given intravenously is 25 million organisms initially, and subsequent doses are increased by 50 million organisms up to a maximum of 500 million. The usual interval between doses is 4 to 7 days. The dosage is not absolute and is varied to suit the patient. If the initial dose does not cause a reaction, then the second dose is given on the following day; while if the reaction is too severe, the same or a smaller dose is given subsequently. Anaphylactic reactions have not been recorded following this form of treatment. A positive skin reaction does not contraindicate further injections of T.A.B. Protein shock therapy with T.A.B. is, of course, not completely free from risk, and deaths have been recorded, but not from anaphylactic reaction.

Eggs in Water-glass

Q.—Is any detrimental effect attributable to the use of water-glass as a preservative for eggs when these are used in the treatment of duodenal ulcer? Is there any reliable alternative?

A.—No detrimental effect is attributable to the preservation of eggs by water-glass for any person well or ill, and so far as is known the nutritive value of eggs so preserved is not significantly reduced. The water-glass fills the porous parts of the shell but does not penetrate the egg membrane. It makes the egg air-tight and thus prevents oxidation and deterioration. Water-glass is the best known egg preservative for domestic use. Other methods extensively used on a commercial scale are treatment with mineral oil and cold storage.

Falling Hair

Q.—Two years ago a young woman's hair became thin on the frontal half of the crown of the head. The condition has not altered since; the scalp looks healthy with only a minimum amount of dandruff. Concurrently with the fall of hair she gained 2 stones (12.7 kg.); she now weighs 9½ stones (60.3 kg), and her weight remains stationary. There is no other apparent glandular abnormality. Ultra-violet irradiation of the scalp has had no effect. What other treatment do you suggest?

A.—Treatment in this case depends on the particular diagnosis. It is presumed that the fall of hair was not associated with any acute inflammation of the skin (such as erysipelas) or with any acute illness at the onset; that there is no present disease, especially about accessory nasal sinuses; and that the condition is not merely one of trichotillomania. The latter is a hysterical habit of pulling and breaking the hair and has an emotional basis. The probable cause in this case is endocrine, and further investigations along this line would seem to be indicated, especially in relation to the pituitary. The condition is certainly not a local disease of hair or scalp.

If hirsuties were an additional feature, this case might be one of the adreno-genital syndrome, in which there is an excessive secretion of androgens, and the woman loses the hair of the head along the same lines as men normally do, while at the

same time there is an increased growth of hair on the face and body. Should hirsuties not be present the symptomatology does not fit into any well-defined endocrinopathy. However, a weight-reducing diet, together with thyroid and the inunction of oestrogens locally, might prove of benefit. (See also "Any Questions?" March 19, 1949, p. 510.)

Refrigeration of Foodstuffs

Q.—What are the public health regulations, if any, in regard to refrigeration of foodstuffs? Are there any types of refrigeration plant which are unsuitable for the cold storage of fresh meat?

A.—There are no public health regulations concerned with the refrigeration of foodstuffs. A local authority can, if it likes, provide cold storage if it sets up a municipal slaughterhouse or market; a laboratory which examines milk must also have suitable cold-storage accommodation for keeping certain samples. A food trader is at liberty to keep food in cold storage or not as he thinks fit. The temperatures employed and the type of plant—as, for example, those with through ventilation and those charged with carbon-dioxide gas—depend on the particular article of food dealt with and the purpose for which it is being frozen or stored. There are no commercial types of plant which are unsuitable for the cold storage of fresh meat, though those with through ventilation may cause some shrinkage and loss of weight of the meat.

Necrobiosis Lipoidica

Q.—A woman aged 24 has necrobiosis lipoidica—confirmed by biopsy—covering an area of about 2 square inches (12.9 cm.) over the middle third of the tibia. Is there any treatment?

A.—Necrobiosis lipoidica was originally thought to be limited to diabetics, but it has since been shown that this is true only in 90% of cases. It is, however, worth noting that this skin disease may precede the onset of diabetes mellitus by years or months. In the absence of evidence to the contrary, it is assumed that the patient in question is one of the 10% who are not diabetic. There is no specific treatment for necrobiosis lipoidica; the condition often appears to be self-limited, and the lesions commonly disappear leaving white scars. If ulceration or secondary infection takes place this complication will require conventional treatment. In diabetics careful control of the metabolic disorder is essential.

Dieting and Birth Weights

Q.—Can dieting by an expectant mother have any effect on the weight of the baby at birth?

A.—Under normal conditions there is no correlation between the birth weight of the baby and the maternal diet, or between birth weight and the maternal gain in weight, in pregnancy. Since the foetus is parasitic, diet restriction within reason does not result in small babies, nor does overeating produce large babies. The only circumstance which will affect the baby is severe and prolonged maternal starvation, and even then the birth weight of the child is not always significantly reduced.

Dry Grass Dust

Q.—Is the dust which arises when grass is baled out of a grass-drying machine, if inhaled over a long period, likely to be detrimental to the health of the operator? Could it affect the lungs or cause dermatitis?

A.—The term "grass" embraces any plant of the order Gramineae. It must be assumed that the inquiry is concerned with dust evolved during the baling of ordinary meadow grass from British fields. No cases of respiratory or skin disease through the breathing or handling of the dust from British grasses have been traced in the literature. However, it is well known that some persons are allergic to pollen, which may be the cause of hay-fever. Some of the grasses which by their pollen cause hay-fever are Bermuda grass (*Cynodon dactylon*), Johnson grass (*Sorghum halapense*), and Timothy grass (*Phleum pratense*). The handling of gramineous plants has been known to cause skin irritation in susceptible persons—a papular exanthem with itching, often accompanied by fever, which lasts between six and twelve hours. Rosniti mentions several

gramineous plants which have caused epidemic dermatitis. Twenty-five members of seven families suffered from erythema after having cut sorghum (Hofter). The admixture of the dry dust of grasses with air may constitute an explosive hazard if exposed to a source of heat.

NOTES AND COMMENTS

Keloid.—Dr. H. P. PICKERILL (Wellington, New Zealand) writes: In "Any Questions?" (Feb. 26, p. 377) various forms of treatment for keloid are discussed. There should be, and is, only one form of satisfactory treatment for this condition—namely, excision and grafting. Excision alone is often unsatisfactory if there is any introduction of tension. Remnants of keloid remaining also seem to induce recurrence. It is necessary to excise widely and deeply, just as though a locally malignant tumour was being dealt with. Radiation sometimes produces a reduction in the size of a keloid, but never its obliteration with an acceptable cosmetic and functional result. Radiation, moreover, leaves the tissues in a very unsatisfactory condition for subsequent plastic surgery. Very large keloids can be treated by excision and replacement by a whole thickness or thick split skin graft, care being taken that in the latter case due allowance is made for subsequent contraction. A post-operative period of immobilization in extreme flexion for extensor surfaces, followed by massage and passive movements, will practically always give good functional and cosmetic results. It would save patients much disappointment if plastic surgery were always considered first instead of as a last resort in the treatment of keloid.

Pig as Vector of Ascaris.—Professor R. T. LEIPER (Director of the Commonwealth Bureau of Agricultural Parasitology, St. Albans) writes: In "Any Questions?" (April 23, p. 735) it is correctly stated that the pig strain of *Ascaris lumbricoides* does not normally develop to maturity in man. That embryonated eggs from pig faeces hatch in the human intestine and the larvae migrate through the lungs was demonstrated experimentally by Koino in 1922, although in the human intestine they failed to develop further. Similarly embryonated eggs of the human strain of *Ascaris lumbricoides* hatch in the intestine of the pig and migrate through the lungs. It cannot therefore be maintained either that the pig "plays a part in the dissemination of eggs of *Ascaris lumbricoides* which have been ingested previously with human faeces" or that there is no risk from the use of manure from pigs naturally infested with *Ascaris lumbricoides*. The differential diagnosis of the bronchial irritation, spastic cough, and pulmonitis which accompany the migration of ascaris larvae of the human strain is very difficult, depending as it does on the discovery of the larva in the sputum, and has seldom been made even in countries where massive infections occur. No one has yet claimed to have diagnosed a case in this country. But it does not follow that bronchial or pulmonary symptoms due to the swallowing of embryonated eggs of either pig or human strain do not occur here.

Warning to Hospitals.—Dr. JULIUS BURNFORD (London, W.1) writes: During the past two or three months I have received case reports on a man by name Leonard Bradford, age 41, giving an address at Vauxhall Bridge Road, or Vauxhall Road, Westminster, from five hospitals into which he got himself admitted, telling of a fit or attack of unconsciousness. He presents symptoms of diplopia; slurred speech; eccentric pupils; sometimes a spastic right limb, at others a coarse tremor. He says he was diagnosed as encephalitis at the West London Hospital two or three years ago, under me. After one, two, or three days when investigations are about to be made he discharges himself and reappears in another hospital with the same story. Reports have come to me from the Hammersmith Hospital; London Temperance Hospital; University College; Queen Mary's Hospital, Stratford; and within one week of the latter from the General Infirmary, Macclesfield. I have sent these to Scotland Yard, and the local police advise me that, on admission in future, the hospital concerned should inform the police and they could then deal with him. As I have not been active at the West London Hospital for ten years he can know nothing about me.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JUNE 25 1949

THE SECRETARY REPORTS

VISIT TO CANADA

Dr. Dain and I have just paid a flying visit to Canada to represent the Association at the first meeting of the Commonwealth Medical Conference held at Saskatoon, Saskatchewan. The conference was the outcome of a meeting held at B.M.A. House in September last at the suggestion of the Association. For many years there was a standing committee of the Association called "The Dominions, India, Colonies, and Dependencies Committee," although in recent years the committee dealt only with matters relating to the Colonies and Dependencies. At the Representative Body the committee was given a name more related to its actual work, "The Colonies and Dependencies Committee." The main subject of last year's conference was the consideration of the problem as to how best to establish a closer link between the medical associations of the Commonwealth, both those within the Association and those with which the Association is affiliated. Hitherto the link has consisted mainly of correspondence between secretaries, exchange of journals, and representation at congresses. The representation to congresses has usually been by practitioners who happened to be going to the place of meeting.

Among the suggestions made at last year's conference for closer liaison within the Commonwealth were social contacts, exchange of lecturers, fuller exchange of information, more inter-Commonwealth opportunities for postgraduate education and reciprocity within the Commonwealth. Eventually the conference drew up a list of proposals to submit to the various Commonwealth units, the more important of which were:

- (1) That it is desirable to develop closer personal and professional relations through their national medical associations or units between the nations linked in the Commonwealth.

- (2) That to this end an endeavour be made to hold a conference of representatives of the national medical associations or units once a year.

- (3) That the first conference be held in Saskatoon, Canada, immediately prior to the council meeting of the Canadian Medical Association.

At the Saskatoon conference, which was presided over by the then President-Elect of the Canadian Medical Association, Dr. Jack Anderson, all parts of the Commonwealth were represented. Those attending were: Dr. William Magner, then President of the Canadian Medical Association; Dr. Harris McPhedran, Chairman of the General Council of the Canadian Medical Association; Dr. de Silva, President of the Ceylon Branch of the British Medical Association; Dr. P. J. Delaney, Secretary of the Medical Association of Eire; Dr. S. C. Sen, Honorary Secretary of the Indian Medical Association; Dr. Howard Drover, of Newfoundland; Dr. J. O. Mercer, Chairman of the Council of the British Medical Association, New Zealand; Dr. J. G. Hunter, General Secretary, Federal Council of the British Medical Association in Australia; Dr. N. Ahmed, President of the Pakistan Medical Association; Dr. A. H. Tonkin, Medical Secretary of the Medical Association of South Africa; Dr. E. S. Dismorr, Honorary Secretary of the Mashonaland Branch of the British Medical Association; Dr. Dain, and myself.

The cost of the conference was borne by the various associations or units represented, in proportion to their capacity to pay, this capacity being measured by their subscription income. This meant, of course, that the lion's share was borne by the Association.

Problems in the Commonwealth

This was the first time that representatives of a Commonwealth association and units had met together, and for this reason it was an historic occasion. But more than that it

was a remarkably successful and useful conference. The general plan at four of the six sessions was to begin with an authoritative statement on the Canadian position or attitude on a particular problem, and then to proceed to exchange ideas and experiences on the subject under discussion. Medical licensure, hospitalization services and problems, experimental health insurance schemes, medical care of veterans, health legislation, undergraduate and postgraduate medical education, the organization of a national medical association, and the future of medicine generally, were among the subjects discussed. We learnt a very great deal about the problems confronting the profession in the Commonwealth countries and their reaction to them, and we were able to dispel a great deal of misunderstanding about the position here. I propose to include in this column in the weeks ahead some summaries of the various contributions made to the conference.

Organized Medical Services

The Commonwealth Conference was immediately followed by the Annual Meeting of the Canadian Medical Association to which the Commonwealth representatives were invited. We were able to sit in during the meetings of the executive of the Canadian Medical Association, the equivalent of our Council, and to the two-day meeting of the General Council, which is the equivalent of our Representative Body. There were differences in the procedure, of course, but, at the same time, there was a strange similarity between the speeches, and those who made them, and the speeches and speakers at our own meetings. The subject which raised the most lively interest was the relationship between the profession and the State and the various ways of meeting what is clearly a growing public demand for organized health and medical services. The bulk of medical opinion in Canada would appear to be for what is called "voluntary contributed medical care," with the emphasis on the "voluntary." There is, however, a growing body of feeling in favour of accepting the compulsory insurance principle for those unable to make provision for themselves. There is general agreement that the costs of hospitalization, as it is called, should be the first to be met by organized provision, though a distinction is drawn between hospitalization which relates to accommodation only, and medical care which relates to the medical services rendered in hospital. In Saskatoon, for example, the Government contributes from taxation to the cost of hospitalization, the members of the hospital staff charging the patients direct for medical care. Canada is clearly anxious to learn from our own experiences, and the one lesson which they have drawn is that, whatever happens, the new order should come in by stages, with hospitalization as the first stage. I gained the impression that the cost of the Service here would, of itself, discourage Commonwealth Governments from proceeding to establish a comprehensive health service in one move.

I need hardly add that the hospitality of the Canadian Medical Association, the Government of Saskatoon, the University of Saskatoon, and, by no means least, the practitioners of Saskatoon was terrific. No president and his lady could have done more than did Dr. and Mrs. Jack Anderson to make the Commonwealth representatives welcome. For myself, I was dazzled by the signs of material wealth which are evident in Canada. Naturally there is a tendency to feel somewhat sorry for the old country, and it was part of the task of the two representatives from this country to remind our colleagues that the old country has a future as well as a past.

National Health Service

PRIVATE HOSPITAL PATIENTS

FORM OF UNDERTAKING

The Central Consultants and Specialists Committee has learnt of cases where patients who have agreed to receive hospital treatment privately have later tried to evade payment for the professional services they have received. Sometimes the specialist has been handicapped in pressing for his fee because there was no written undertaking by the patient.

The Association's solicitors have therefore prepared a model form of undertaking suitable for patients in "ceiling" and "no ceiling" beds.

The model form covers professional fees and maintenance charges. Where the hospital authority is unwilling to include an undertaking in respect of professional fees with the undertaking that it usually requires in respect of maintenance charges the form may be used by the specialist alone with the deletion of paragraph (a).

To Dr (Mr)

I, _____ of _____, request you to make arrangements for the treatment of _____ at _____ Hospital as a private patient.

The Sections of the National Health Service Act, 1946, referring to private patients, printed overleaf, have been brought to my notice. I agree to pay

(a) the charges for accommodation provided at the hospital in accordance with the scale in force at the time of the stay in hospital, and

(b)* the charges for services rendered by you or any other medical practitioner in accordance with the scale in force at the time of the stay in hospital,

OR

(c)* the charges for services rendered by you or any other medical practitioner, which I agree shall not be confined to the scale laid down by the Minister of Health under the National Health Service Act, 1946.

ADMISSION TO MEDICAL LIST

APPEAL REJECTED

The appeal of a doctor to the Secretary of State for Scotland against the refusal of the Scottish Medical Practices Committee to admit him to the medical list for Ross and Cromarty was recently rejected. One of the questions at issue was whether a doctor appointed to that list should be able to speak Gaelic.

Dr Donald Macaskill had served as a locum tenens at Borve Outer Hebrides, for eighteen months, and applied to be appointed as medical officer in the district. There were also a number of other applicants. The appeal was presided over by Mr J G Leechman, KC. Witnesses from the district in support of Dr Macaskill suggested that a Gaelic-speaking doctor was necessary there. Others appearing for Dr Henderson held that Gaelic was unnecessary. Sir William Marshall, representing the Scottish Medical Practices Committee, said that the committee considered that in such a large and isolated area there should be an experienced practitioner, and the executive council had done right in appointing Dr Hector Henderson, of Fraserburgh, who was a practitioner with very wide experience. He emphasized that there was no reflection whatsoever made on Dr Macaskill, but, he said, Dr Henderson was a more experienced man.

The Secretary of State for Scotland rejected Dr Macaskill's appeal, and sustained the appointment of Dr Henderson.

GENERAL-PRACTITIONER SPECIALISTS

Now that the deliberations of the regional review committees are becoming known, a large proportion of general practitioners practising also as specialists are finding themselves placed in the senior hospital medical officer grade. It is as well to remind these practitioners therefore of the appeal procedure now granted by the Ministry, following representations by the Joint Committee.

Appeals should be made before July 4, or, if the assessment of the review committee is not notified to the practitioner by that date, within 14 days of the receipt of notification. In the case of an appeal so made, any upward revision of status will apply retrospectively to July 5, 1948.

Apart from the possibility of upgrading on appeal, senior hospital medical officers will be free to apply for future specialist appointments and thus to regain or obtain specialist status by selection for the appointment in open competition by an advisory appointments committee. In addition, the Central Consultants and Specialists Committee has recommended that there should be a periodic review of senior hospital medical officers with a view to upgrading in appropriate cases.

Inquiries have been received from "downgraded" members of hospital staffs whether, in view of the retrospective application of the permanent terms, they will have to refund any part of the salary they have been receiving during the interim period. It is clear from the "Explanatory Memorandum" (*Supplement*, June 11, p 321) issued by the Ministry that, where the interim salary exceeds the salary to which the officer will be entitled retrospectively, regional boards should not attempt to recover the excess.

In some instances general-practitioner specialists have been notified that the review committee has not been able to place them in any grade, and in these cases the practitioners naturally are anxious about the continuance of their hospital work. It is likely, however, that in a substantial proportion of these cases the hospital authority will wish to retain the services of the practitioner, and indeed for the present may find it necessary to do so. Practitioners in this position are therefore reminded of the provisions of the Terms of Service relating to the engagement of general practitioners as "clinical assistants" or in other capacities at the rate of remuneration of £175 per half-day, and are advised to inquire of the board whether employment in this category will be offered.

HOSPITAL STAFF TERMS

The Ministry of Health has issued some small revisions of the "Terms and Conditions of Service of Hospital Medical and Dental Staff (England and Wales)," which appeared in the *Supplement* of June 11 (p 314). Among the more important are the following.

Section 12, para (b) "Boards or hospital management committees" Delete "or hospital management committees"

Section 16 In the last line of the first paragraph the word "services" should be "appointment". In the third line of the second paragraph "part-time" is deleted from before "consultants services," and the sentence should continue, "the board recognizes that it has a moral obligation to render the greatest possible assistance to the consultant with a view to his obtaining comparable work in another hospital."

Section 18, para (a) The word "holiday" is deleted from the heading "Annual Holiday Leave"

Section 18, para (e), sub-para (2) (c) "shall not exceed the officer's normal monthly salary" should be "shall not exceed the officer's normal salary for the period"

Section 18, para (e), sub-para (2) (d) After the words "The benefits" should be added "compensation payments and allowances"

Section 18, para (e), sub-para (2) (f) The first clause should read "For the purposes of calculation of allowance"

Section 18, para (e), sub-para (3) (f) The words "the sum refunded should not be recorded for the purposes of this scheme"

should be "the sum refunded should not count against the officer's sick leave entitlement."

Section 18, para. (e), sub-para. (3) (h). The following clause should be deleted: "... but without prejudice to the right of an officer whose employment is terminated by reason of permanent ill-health or infirmity to receive the period of notice provided by his contract of service."

Section 19, para. (d) (i). The words "Ordinary mileage allowance" should be "The appropriate mileage allowance under (c) above."

HEARD AT HEADQUARTERS

The Private Bed

The Dean of St. Paul's, who spoke the other day at St. Luke's Hostel for Clergy, remarked that a year or two ago he had to spend a considerable time in hospital as a patient. He had a private room. "In those days," said Dr. Matthews, "I was able to afford the sum required to have some little privacy in my illness, but I am not so sure whether I could afford it now, because, as usually happens when nationalization comes on the scene, prices have gone up, and the cost of that private room has almost doubled." He added that he did not know why this should be, and he was anxious about the large number of people of moderate means to whom privacy in illness is a thing as much to be desired as medical and nursing attention itself.

Whither Medicine Bottles?

If Sir Stafford Cripps wants to save money on the Health Service he might start with medicine bottles. Some millions are handed over to patients every year and each one costs the taxpayer between about a 1d. and 3d. Few ever find their way back to the chemist, yet probably most could be recovered if the patient were charged the cost of the bottle when he collected it and that sum were refunded if he returned it. Their fate at present is a mystery. Perhaps some patients drain the precious liquor eagerly and in an ecstasy of rejuvenation dash the bottle to the floor. Others no doubt throw them furtively into the dustbin. The worried may gradually accumulate them under the stairs, in the attic, or in a kitchen cupboard and occasionally allow a favoured visitor to glance over them, as others display their library. We have heard that in rural districts they are often to be seen early in the year being used for feeding lambs. At any rate, most people would be only too glad to return them to the chemist if they felt that their action would save a little money and help to restore the dollar balance.

Telling the Patient

An educated lady of our acquaintance recently had occasion to consult her doctor, who found that she had high blood pressure. Being "up" on this subject, and knowing all about systolic and diastolic and so on, she asked him, to tell her exactly what the reading was. He hesitated, and at first refused, but eventually yielded and told her exactly what the sphygmomanometer had recorded. She intimated that if he had not done so she would have refused to pay his fee. That might have opened up an interesting legal argument. The practitioner could surely claim that he was called in to treat the patient, and that it was in no way necessary to her treatment that she should be informed of diagnostic details, but whether that would avail in the county court is another question.

Medical Ethics

The Central Ethical Committee of the Association has carried out a useful task in bringing together ethical rules for doctors in extension and elaboration of those which form the subject of Warning Notices by the General Medical Council. Admittedly a practitioner's conduct cannot be regulated by formal rules; it would be deplorable if it could. The rules are rather illustrations of the general principles of behaviour which the good doctor will intuitively observe. One of the rules states that "the announcement of lectures to be given by a doctor should not in any way be laudatory of him." No doubt this

refers to the public advertisement of lectures; if the doctor is to be in peril because of a chairman's fulsome introduction of him it is a forbidding prospect.

Research Subsidies

Medical research in the United States proceeds on a scale which makes British laboratories envious. When Dr. Earle Moore, of Baltimore, lectured the other day to the Medical Society for the Study of Venereal Diseases he was asked how they managed to secure the large sums necessary to pursue the investigations he had described. Dr. Earle Moore confessed that venereal diseases is not a subject which attracts philanthropy. The philanthropist who subsidizes research into particular diseases generally chooses diseases from which he or his family are suffering or are liable to suffer. But the second world war made it apparent to the United States Government that venereal diseases affected the national economy, and now the Public Health Service is allocating about one million dollars a year for this research, appropriated through the Subcommittee on Venereal Diseases of the National Research Council and the Syphilis Study Section of the National Institute of Health. During the present year about 400,000 dollars is being spent by the Syphilis Study Section. One real danger in these researches, not limited to venereal diseases, was pointed out by Dr. Earle Moore—the danger that prophylaxis or treatment (by penicillin in the case of venereal diseases) may be so simplified as to become a routine and to turn the doctor into a mechanic. As he put it, the patient's needs are met only 10% by sticking a needle in his body; 90% of his need is for the physician's skill in dealing with the patient's problems and outlook.

Questions Answered

Superannuation

Q.—I have employed as a part-time assistant a doctor who has a small practice of his own near-by. He was with me before July 5, 1948, and then carried on having joined the N.H.S. himself. I was permitted to continue employing him as it was agreed that a principal could also act as an assistant. Should the 8% superannuation contribution towards his pension have been deducted from my remuneration cheque? Since he is a principal in his own right, should not the Ministry pay his 8%? The 6% contribution was also deducted from me, but this, I understand, is correct and can be claimed from the assistant.

*A.—*There are two separate contracts here. As a principal your colleague is under contract with the executive council, which is the "employing authority" for superannuation purposes. As a part-time assistant his contract is with you, and, in respect of the services he renders to your patients, you are the employing authority and are responsible for (a) recovery of the 6% of his remuneration for remission to the executive council, and (b) the employers' contribution of 8%.

Superannuation for Assistant

Q.—My salary as an assistant in general practice is £15 15s., less £3 3s. because I am required to "live in." Income-tax authorities tell me the £3 3s. is an allowable expense and tax is levied on £12 12s. per week. Do I pay superannuation on £12 12s. or £15 15s.?

*A.—*Remuneration on which superannuation is payable is defined as "all salary, wages, fees, and other payments paid or made to an officer as such for his own use, and includes the money value of any apartments, rations, or other allowances in kind appertaining to his employment." Superannuation is therefore payable on £15 15s.

Fees under Road Traffic Act

Q.—Has payment of medical fees under the Road Traffic Act been affected by the National Health Service?

*A.—*Notwithstanding the introduction of the National Health Service, medical fees may still be claimed under the Road Traffic Act.

THE GENERAL-PRACTITIONER CONSULTANT

BY

G. LOWE, M.B., F.R.C.S.Ed.*Honorary Surgeon, Tiverton and District Hospital*

AND

T. N. RUDD, M.D., M.R.C.P.*Honorary Physician, Tiverton and District Hospital*

The events of the last few months have focused the light of investigation upon the hospital service of the United Kingdom, the doctors who work in them, and the practitioners who send them cases. So far as the smaller hospitals are concerned the status and the manner of payment of the medical staffs are being carefully considered, while in the case of the larger non-teaching hospitals staffed by pure consultants the point at issue is whether it is undesirable to introduce gradually a system of full-time salaried consultants, with the probable end-result of the ultimate elimination of the part-time consultant, who is employed in the remainder of his time in private consulting practice.

But while these important decisions are being made general practitioners throughout the country are viewing with some disquiet certain tendencies in hospital practice which seem to lead to the exclusion of the G.P. from the case he has referred to hospital. They feel that once they send a case to hospital they lose all contact with it, fail to obtain progress reports from hospital officers, and at the end learn nothing of the results except through the patient's relatives, who, imagining that their doctor has been fully informed throughout, impute his ignorance to disinterest and blame him accordingly. Such doctors have found the hospital consultants inaccessible or not informed of the latest developments in acute cases, and report that housemen too often consider the inquiring G.P. a nuisance, so that the only source of information of their patient's progress is the ward sister. An alteration in the consultant's source of income may be partly to blame for this. When this was derived, as in the past, from private cases referred by G.P.s, consultants saw to it that the G.P. was kept in the picture. Now that the consultant is being paid largely by the State, the G.P. as a source of private work has fallen in importance.

While there are many hospitals whose medical staffs have impeccable manners, it is probable that this failure to keep the G.P. in the picture is occurring on an increasing scale, and that the problem should receive the attention of all honorary staff committees. Its importance is obvious, for the ultimate result of the hospital's work depends so much on the home doctor who has to carry out the after-care and treatment prescribed by the hospital consultant. The integration of medical practice, which should be the theme of the N.H.S., demands that hospital and family doctor shall work together, each giving the other his proper place in the national Service.

There is, however, one old-established link between general practice and the hospital consultant service whose future has been jeopardized by modern administrative tendencies and whose elimination from the nation's medical service could not fail to have far-reaching effects of an ill nature. This link is the general-practitioner specialist, whose position is still much misunderstood. There are about half as many of these as there are of full-time consultants. Much has been written of late for and against his retention. In a recent paper (Lowe and Rudd, 1948) it is stated: "However much or however little surgery any part-time surgeon may undertake, it will be readily agreed that the total volume of work undertaken by a specialist of this type is very considerable." We think this is indisputable, that it applies to part-time G.P. specialists in all departments, and that elimination of the G.P. specialist would have a considerable influence on the future of the smaller hospitals, almost entirely for the worse. This feeling will be shared by the general practitioners who sense already that many of the larger hospitals are "cumbered with much serving" and have lost the personal interest which views the patient in his permanent environment—i.e., his home and occupation. They view with some apprehension the possibility that the G.P. consultants will be displaced from their positions in favour of the resident

hospital specialist with no local interests, or the visiting junior from the larger centre some miles distant.

Source of G.P. Consultant

Before the problem of staffing the smaller and rural hospitals is examined the source of the G.P. consultant should be considered. Too often it is assumed by doctors whose experience has been confined to larger towns that the G.P. consultant is primarily a G.P. with a special medical interest, who "learns as he earns," whose specialist training and experience is inconsiderable, and who, now that specialist hospital contracts are being offered, "for their bellies' sake creep and intrude and climb into the fold" of consultant practice. It is vital that this point of view should be corrected. There are three means by which the G.P. consultant reaches his status:

(1) The man with postgraduate qualifications and experience, of registrar status, who enters general practice (usually for economic reasons), and who practises his specialty on the staffs of a smaller or larger hospital continuously from his entry into general practice, and who by his standard of work gains the confidence of the non-specialist G.P.s of the area. This method of practice has proved invaluable in absorbing the larger quantity of juniors of specialist status who have been unable to secure staff appointments to the larger hospitals.

(2) The man with G.P. qualifications who gained considerable experience in his specialty during his war service.

(3) The well-trained G.P. without postgraduate qualifications who has gained considerable skill in some specialty during his years as a G.P. and hospital doctor and who has supplemented this by postgraduate courses or other special studies. These are the "learn as you earn" class, a small body of men, many of whom are highly accomplished but who by the nature of things are most unlikely to be replaced once they have died out.

The bulk of G.P. consultants fall into Class (1) and fulfil the four generally acknowledged postulates for consultant status. To quote again from Lowe and Rudd (1948), these are:

- "(1) Specialist experience in the department concerned.
- "(2) Postgraduate qualification of recognized standard in the specialty.
- "(3) Recognition by other practitioners as being a specialist."

to which must now be added:

- (4) Sufficient time continuing to be spent in sessional work in hospital to maintain his efficiency.

Between the cottage hospitals, with their open staffs of local G.P.s and the larger hospitals with their staffs of pure consultants there are a number of hospitals of intermediate size, often many miles distant from the large towns, which are at present staffed by G.P. specialists who fall into one of the groups set out above. Three methods of staffing these hospitals are apparent: (1) By G.P. consultants or specialists, as at present; (2) by full-time salaried specialists; (3) by visiting specialists from the staff of the next largest hospital. The pros and cons of these alternatives are set out below.

I. FULL-TIME SALARIED SPECIALIST STAFF

For: Such a staff may be more efficient than a G.P. consultant staff because there is no division of interests, the specialist or specialists being able to devote all their interests to hospital specialist duties.

Against: (i) Such staffing is uneconomic, as at most smaller hospitals it would not be possible to employ a resident specialist in each major department.

(ii) Such a service would be much less "personal" than a staff of G.P. consultants living among their own patients and feeling responsible for them. This lack of a "personal" service, so important in medicine, would be increased by the probable frequency of specialist staff changes leading to a lack of continuity.

(iii) The medical profession has already expressed itself as opposed to a full-time salaried service, of which this would be a beginning.

II. VISITING CONSULTANT STAFF

Derived from next larger centre, the routine duties being carried out by house-surgeons and house-physicians or alternatively by local G.P.s.

For: (i) Possible increased efficiency.

(ii) Improved liaison with the larger hospital centres.

Against: (i) As senior consultants are already either fully occupied in their own hospitals, and in domiciliary consultant work, or already work the maximum number of specialist sessions allowed by the

regional hospital board, duties in the peripheral hospitals would probably fall on less experienced junior men, who might have to be found and specially appointed for this work.

(ii) Unless these men had considerable G.P. experience they would be more likely to handle their patients as "cases" rather than as persons, and treat the disease rather than the patient. They would thus be less acceptable to the public than the local G.P. consultant, who has to live among his patients. A hospital with an impersonal approach soon loses its good reputation. All G.P.s know how difficult it is to induce patients to accept hospital treatment unless they have full confidence in the hospital.

(iii) Such appointments to smaller hospitals are likely to be for short terms, so that frequent change of specialist personnel is to be expected.

(iv) The suggested system does not solve the problem of surgical emergencies. To move the patient to the surgical team at a larger centre 15 or 20 miles distant is economic, but likely to be unpopular with patients who have the right to all reasonable medical or surgical treatment in their local hospitals. On the other hand, to bring the surgical team to the patient will often be difficult and may occasion considerable delay, to the patient's detriment.

III. STAFFING BY THE GENERAL-PRACTITIONER CONSULTANT

Against: (i) The principal argument against the G.P. consultant is the fact that he does not spend all his time working in his specialty, so that he may not be quite so efficient as his colleague who works full-time therein.

(ii) The other arguments against him have been set out elsewhere (Lowe and Rudd, 1948), and include unevenness of standards, charges that he undertakes work beyond his capacity, and that, being overburdened with duties of a non-specialist nature, he is unable to keep abreast of advances in his department.

The answers to these objections and the arguments in favour of the G.P. consultant on the staff of smaller hospitals are set out last, as it is hoped to show that this method of staffing is likely to be the most satisfactory alternative in rural areas and smaller country towns.

For: (i) The G.P. consultant is relatively more responsible to his patients and is more readily blamed by them if something goes wrong. He has to live with his mistakes and therefore not take unnecessary risks involving adverse results or death, but he must maintain the confidence on which depends the reputation by which he earns his living. He must therefore "pass on" all doubtful cases or call in more skilled assistance.

(ii) He has his own team on the spot for dealing with surgical emergencies at any time, day or night.

(iii) He is more acceptable to local residents, who tend to trust him because they know him.

(iv) He is almost bound to give more personal service than the young full-time specialist who has no roots in the place; he will usually stay longer—perhaps a lifetime—in the locality.

(v) He inspires the standard of local general practice and thereby strengthens the foundation of the whole medical service.

(vi) The ranks of the G.P. consultant provide a satisfying professional life for the surplus practitioners with higher qualifications who are unable to obtain consultant appointments to the larger hospitals.

(vii) The good G.P. consultant is popular with the local practitioners, for, being a G.P. himself, he understands their particular difficulties and is more approachable than the pure consultant, whom they feel disinclined to worry about problems which may, or may not, be trifling.

(viii) If he is a junior with no great amount of experience of handling patients the stern discipline of general practice, with all the personal responsibility it entails, will keep him on the right lines, so that as the years pass he will steadily become a better doctor, with a more mature opinion, instead of only being a better technician.

In fine, it is suggested that competence and efficiency are not the sole possession of any one branch of the profession, and that the humanizing effect of living close to the patient may at least counterbalance any degree of technique that the G.P. consultant loses through not being wholly employed in his specialty. What he loses in technique he gains in being able to treat the patient as a whole person and not viewing him just as an example of a disease. These points taken together form a very considerable argument in favour of the staffing of hospitals of intermediate size, in selected areas, by general-practitioner consultants.

Certain limitations are, of course, inherent in such a plan. Clearly, the scope of the G.P. consultant and the number of techniques he practises will be narrower than that of the pure

consultant. But within his own field his standard of practice should reach the average of consulting work elsewhere. In all techniques beyond his competence he will co-operate with specialists at higher levels. His other duties must be so balanced that his specialist work does not suffer because of his G.P. commitments. For this reason an association of G.P. consultants in group medical practice would appear to be highly desirable. A report of such an association appeared under the title of "A Medical Group Practice" in the *Lancet* (1948). It is felt that any narrowing of scope inherent in G.P. specialization is offset by the broadening of outlook produced by his G.P. interests.

Surplus Specialists

Apart from the arguments set out above there is the, at present unsolved, problem of using the surplus young doctors of high qualifications and considerable hospital experience who fail to secure appointments at the larger hospitals. There were, for example, 78 candidates for a recent appointment of assistant surgeon to a large non-teaching hospital, while the large entries for the Primary F.R.C.S. (there were 450 at a recent examination) suggests that the supply of young surgeons is not falling off in spite of growing waiting-lists for in-patients and hospital out-patients. Further consultants cannot be appointed in numbers sufficient to deal with these until all hospital departments have expanded considerably, and this expansion cannot occur for 10 to 15 years.

Meanwhile, senior consultants, with too few beds, are tending to appoint registrars as their first assistants, appointments which are bound to be "blind-alley" employments for the great majority of those who accept them, since each consultant may employ in his lifetime eight or ten registrars, only one of whom can succeed him. Examination results for the London M.R.C.P. and the English F.R.C.S. suggest that only 20% of the successful candidates are likely to obtain consultant appointments, while a period spent as a first assistant is unlikely to improve the prospects considerably. What is to be the fate of the unsuccessful 80% of Fellows and Members?

The present time is critical not only for the future of our smaller hospitals, on which depend so many lives in the country area, but also for the future of the highly qualified younger medical men, who would normally be ornaments of their profession. If the economic situation is to deny them hospital employment in the larger centres, three courses only are open:

(1) They can be appointed to the small hospital over the heads of the present G.P. consultants, who far surpass them in experience of medicine and patients.

(2) They can be encouraged to sacrifice their ambitions and become general practitioners without any ability to practise the specialty they have begun to study.

(3) They can be encouraged to enter general practice as G.P. consultants, with recognized status, preferably to work in group practice round a hospital centre.

The objections to the first two alternatives are very obvious and very real. A busy profession dealing daily with life and death has no need to be impeded by the bitterness which either of these would cause. The third is put forward as the ideal solution by a group of part-time consultants who have found a sense of achievement in this method of practice, who are very well aware of its difficulties and drawbacks, but who are convinced that these obstacles can be overcome, to the great advantage of the patient, whose welfare is the alpha and omega of the Hippocratic tradition.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

PLANNING AND WELFARE

SIR JAMES ROSS'S LECTURES ON THE N.H.S.

A series of three lectures on the National Health Service was delivered in May at the London School of Economics and Political Science by Sir James S. Ross, until lately Regional Officer for Health Services, Ministry of Health. The lectures were designed for students of public administration and social science. Professor T. H. Marshall, C.M.G., presided at the opening lecture.

The Historical Background

In his first lecture Sir James Ross began by speaking of his privilege in addressing a university audience in the school whose former director, now Lord Beveridge, in 1942 finally established the place of a comprehensive health service in the social framework of this country. He said that in giving these lectures he had two things in mind—a study in social welfare, and a study in planning and administrative method. He described the National Health Service as part of a thorough reconstruction of our social services and at the same time necessarily a new venture in public administration. Its roots were in the past, but it brought about far-reaching changes in general organization, in the scheme of authorities, and in the method of their appointment and procedure. He asked his audience to think of the Service as something which had a well-knit argument running through it—a service flexible in use and one that could be developed, admitting of alteration in the light of experience.

The Act itself he described as the mandate and the general plan, needing to be supplemented on a large scale by regulation and administrative action. The more detail that was put into an Act of this pioneering character the more was the general discretion of administrators fettered and the greater the hindrance in adjustment to developing needs.

The health provision for this country had fine traditions and a great record, but these were not enough. He quoted from one of the *Hospital Surveys*, 1941-5: "The evacuation of our cities and the findings of our medical recruiting boards have laid bare such a mass of preventable disability, under-nourishment, and poor development that we are ashamed." Statistics showed what the facts were and what could be done. The cost of ill-health in money and national resources was estimated. The inadequacy of the provision was made apparent.

The four main pillars of social welfare, each of them essential to the stability of the others, were education, health, social security, and production. By health was meant not only the study and treatment of, for example, cancer but the planning for health as a positive policy. Notwithstanding the great work of our hospitals, nursing services, voluntary associations, public health service, and general practitioner service, the inadequacy of health provision remained. The general practitioner service had not nearly met the needs of the people. The condition of their teeth was bad beyond words, and there was a wide range of other needs—for the eyes, for rheumatism, tuberculosis, cancer.

Recent Reforms

The Act, as Lord Beveridge had said, first removed completely the economic barrier between sick persons and the best possible treatment for them, and it set up for the first time a true Ministry of Health, a national authority with the duty and power of attacking disease as a national enemy. The lecturer proceeded to a brief review of social history since the beginnings of the social revolution forty years ago, and mentioned the coming of National Health Insurance, local authority health services, the work of voluntary agencies of all kinds, including district nursing associations, the great progress in clinical medicine, the extensions of voluntary hospitals, the rise of the great municipal hospitals following the Local Government Act, 1929, the growth of hospital contributory schemes, and the shaping towards a national scheme of health service, as witnessed in the reports of the British Medical Association on "A General Medical Service for the Nation" and the report of the Sankey Commission on voluntary hospitals.

The pace of reform quickened during the second world war. In 1941 the Beveridge Committee was set up to survey the whole range of social insurance and allied services. In 1942 came the Draft Interim Report of the Medical Planning Commission, set

up by the British Medical Association—a most valuable and reasoned study—and in the same year the Beveridge report, followed a few months later by the acceptance of the Beveridge plan in principle by the Government of the day, including its basic assumption of a comprehensive medical service for all. In February, 1944, the Coalition White Paper appeared, and the Bill was introduced in March, 1946, followed by lengthy debates in both Houses.

Sir James Ross then proceeded, with the aid of an organization chart, to give an account of the structure of the Service. He said that the Minister now had high constitutional responsibility; he was answerable to Parliament for the efficiency of the Service and for the husbandry of its heavy expenditure. This had to be secured through hundreds of authorities, manned by some 13,000 voluntary members, to whom was given the fullest possible administrative discretion and initiative, particularly in the field of hospital administration. He explained the constitution and purpose of the Central Health Services Council and the standing advisory committees. He then dealt in outline with the three sets of regional and other local authorities and with the argument for the regional hospital boards and hospital management committees. Perhaps the most critical factor in the organization was the necessary interaction, in respect of policy, planning, and local practice, between the different sets of authorities.

General Factors in Health Administration

In his second lecture Sir James Ross, approaching the subject as a student of the Service from within, discussed the collective obligations of the authorities and the conditions under which they worked. He bade his audience think of the sheer magnitude and complexity of the task before them. The happiness and welfare of some 45 millions of human beings were involved. What were the resources available?

There were shortages of every kind—in buildings and personnel. Notwithstanding the splendid heritage of the past into which the Service had entered, there were professional shortages. New staffs had had to be found and tried out; new procedures had to be created. All the elements concerned had to learn to work smoothly together, and over a wide range close interworking had to be established. There was an expectancy abroad. It was not only mothers who were "expectant," but fathers and grandfathers. Democracy demanded as did no other form of society that the citizens should understand their institutions and their problems. A common misunderstanding about the Service was amusingly illustrated by the remark of a lady who told her doctor ten days before the appointed day, "Make no mistake; I am going into hospital on July 5. I know my rights."

It was not only the fact that the cost of illness arising as a result of specialization was beyond the purse of the average person. The question was: Could the nation afford it? How much could it afford? Clinical advice was well ahead of their capacity to use it. Perhaps the biggest health factor the Government had to face was the ageing of the population. In 1901 there were in this country 857,000 people of 64 and upwards. In 1948 the number was 4,643,000, and by 1965 the total was expected to reach 5,400,000; 12% of the entire population would be over 64. This meant a greatly increased burden on the community, first because of the higher sickness rate attaching to the elderly, and secondly because of the need in some way to keep these old people fit to earn their living for a further period of years. Here the lecturer commended a small pamphlet, *Matters of Life and Death*, published by the General Register Office, 1948 (H.M. Stationery Office, 1948, 6d.), not only for its information but for its inspiration.

Finally, medicine was working out new lines of strategy and tactics in treatment, not only in the closer interrelation of physical and mental treatment, and on the new balance between individual and social medicine, but on some quite specific points, such, for example, as the development of out-patient departments in the larger hospitals into primary means of diagnosis and treatment by specialists. Another outstanding change was in the hospital treatment of the aged and infirm—that is to say, the endeavour to make people who would otherwise remain chronically ill for the rest of their lives walk again on their own good legs after a stay of a few weeks in hospital. Again, there was the question of a quicker turnover of patients. These

questions would in large measure condition and determine the plans and practice prevailing in the future.

Sir James Ross then went on to describe the hospital and specialist service, the working of the 14 regional hospital boards each with 20 or 30 or perhaps 50 hospital management committees in its area. Alongside these were the teaching hospitals administered independently by boards of governors of their own. All this was an original and courageous contribution to the health service of the future. He discussed the reasons which had made this revolutionary change of ownership and management necessary.

He dealt also with the mental health services, the new mandate under which local health authorities were proceeding, the plans for health centres, and the place of the nursing profession in the National Health Service.

Family-Practitioner Services

In his third and final lecture Sir James Ross discussed in particular family practitioner services. Describing first the executive councils, he said that such councils existed in each county or county borough (unless there was a link-up of adjoining areas). A council consisted of a chairman and 24 members—12 lay and 12 professional. Of the lay members, 8 were appointed by the local authority and 4 by the Minister. The professional element consisted of 7 doctors, 3 dentists, and 2 pharmacists. The widest consultations had been made regarding suitable chairmen to start with, and care was taken to avoid arbitrary action and to consult democratic opinion in setting up these important bodies.

The executive councils were the heirs at law of the old insurance committees, but with wider duties and a larger professional element. Alongside them were the local professional bodies in each area, all recognized in the body of the Act itself. The actual working of these councils was through committees. There was no separate representation of interests. It was stressed at the beginning, "Please forget where you come from." The idea was that each member was there to contribute his experience to the solution of common problems.

Finance of General Medical Services

The provision of £102 million included £2 million for administration, £40.5 million for the general medical practitioner service, and £19 million for pharmaceutical, £28.5 million for dental, and £12.5 million for ophthalmic services. Thus the doctors and their prescriptions cost not quite £60 million. The Service included now over 13,000 general practitioners (principals), and more than 40 millions of the population were on their lists. The system rested upon free choice of doctor and of patient. All proper and necessary treatment was afforded short of treatment calling for the application of special skill or experience of a degree or kind which general practitioners as a class could not reasonably be expected to possess. The assurance was given that there would not be two qualities of service but one uniform quality throughout the country. It was true that since the Service started there had been many trivial calls on doctors, but there had been also many cases of illness hitherto undisclosed. The heavy strain on the doctors, with their crowded surgeries, was acknowledged. The public must learn forbearance and common sense. This was a real test of the quality of our people.

Doctors were distributed unequally. In Richmond, for example, there was one doctor for every 1,400 people, and in South Shields one for every 4,000. For the better regulation of this a Medical Practices Committee had been constituted, six of whose eight members were doctors. There was an inducement fund amounting to £200,000 to encourage doctors to practise in less favourable areas. He described also the subsidy system obtaining in the Highlands and Islands, and the mileage payments. Another important central body was the tribunal to deal with such disciplinary matters as inevitably arose in the administration of the Service. Its chairman was appointed by the Lord Chancellor.

The provisions of the amending Bill recently published were mentioned, and the way in which it met the fears of doctors with regard to the possible imposition of a State salaried service. The medical profession was still exercised about the financial aspect and was claiming a much higher betterment factor. Another matter for consideration was whether the capitation

fee should be graded, with a higher rate for the first 1,000 persons on the list. The important thing was to ensure a high standard of general medical practice. This was the keystone of the arch.

The maternity medical service involved the provision of a special list of general-practitioner obstetricians. About 55% of doctors had their names on that list. The expectant mother might choose any doctor from that list, and a midwife would be engaged in the usual way. The essence of this service depended upon the two working together harmoniously.

Nearly 900,000 old people were wearing glasses who had never had their eyes tested before, and about 2,000,000 had had no test for over five years.

General Finance, Priorities, Standards

Dealing with the finance of the Service, Sir James Ross said that the original estimate in 1946 was simply a shot in dim light. He gave the figures for 1949-50. The inevitability of the rise in estimates was generally admitted. What about economies in administration? It had been truly said that we want a science of medical economics. There were some basic items of expenditure which were not in question. Beyond these essentials what were the priorities in the long view?

In some things nothing but the highest standards could be afforded. It was not possible, for example, to economize on the standards of teaching hospitals. What other services can manage on less costly standards and scope? The immediate problems were not of supply but of allocation and use. "We have got to get the maximum healing power from the resources available. There is hardly any element in the health services in respect of which we could not do with a great many more facilities than we have at hand."

In conclusion, he referred again to the new outlook on the question of the aged and infirm, and spoke in terms of high appreciation of the report of the Special Committee of the B.M.A., *The Care and Treatment of the Elderly and Infirm* (1947, 3d.), only urging that instead of the ugly word "geriatrics" the beautiful Greek word "eugia" be used.

Two other typical problems for lay administrators were those of rheumatism, representing a loss to industry of something like £40 million a year, and tuberculosis. He emphasized the need for a continuance of voluntary service. Any person of good will could find immediate work to do in connexion with the health and welfare organization. The voluntary associations should get together in their own districts and ask the medical officer of health what part in the Service they could best play on a voluntary basis.

FACULTY OF OPHTHALMOLOGISTS.

At the Faculty's Council meeting on April 29 the following officers were elected for 1949-50: President, Mr. Frank W. Law; Vice-President, Mr. J. J. Healy; Honorary Secretary, Mr. J. H. Daggart; Honorary Treasurer, Mr. A. B. Nutt.

It was learnt that the practice of referring patients from the hospital clinics to the Supplementary Ophthalmic Service did not meet with the approval of the authorities. It was agreed to write to the Ministry stating that the Faculty did not approve of this practice, but until more assistance, technically and financially, was received towards the progress of the permanent service there did not appear to be any alternative. It was also decided to point out that the prescriptions of the patients seen in hospital must be made up in the hospital, otherwise there would be no saving financially.

The draft handbook for ophthalmic medical practitioners and ophthalmic opticians, together with the comments of the Ophthalmic Group Committee, was considered. The Ophthalmic Group Committee's comments were approved, but it was felt that it should be illegal for an optician to prescribe glasses for any case which had been referred back to the general practitioner. It was decided to recommend to the Ophthalmic Group Committee that representatives from the committee and the Faculty should discuss this point with the Ministry, and the chairman of the Group Committee and Mr. Law were nominated to act in this capacity.

At the suggestion of the Ministry of Health a Committee of Referees is to be set up to deal with matters arising from

certainly not be a "strike," but merely his unwillingness to buy from us something (services) on terms which everybody would concede are wholly reasonable from our point of view.

It may be argued that we are going against the Government in demanding this. Such is not the case. Suppose we were a contracting firm approached to build a colossal undertaking for the Government. Would our contract state exactly what we were to be paid for the job, or would it leave to the Minister concerned the right to reduce our price at his will? Would any business firm sign a contract on such terms? Certainly not. Very well; why should we be asked to? And if asked to, why should we be such fools as to agree?

There is one further amendment which I urge all consultants and specialists to insert before signing, and to insist upon before taking up duties. It deals with the tenure of the appointment, or, put in another form, the right of determination of the contract. According to the Minister's proposals a consultant who considers that his appointment is being terminated unfairly by a board shall be entitled to appeal, but that appeal must be completed before the board's decision to terminate the appointment is carried into effect. This gives to the boards an advantage which is quite unfair.

If they were to give a specialist a month's notice he might have time to get his appeal dealt with in that time. If three months' notice was given there should certainly be time. But suppose that in order to prevent the specialist from making his appeal the board summarily dismisses him, at the same time covering themselves from any action for wrongful dismissal by paying him a month's salary in lieu of notice, then he cannot appeal—at least so it would appear.

For that reason I again most strongly urge every consultant and specialist in the country to refuse to enter into contract with the Minister until the contract is so worded as to secure (except perhaps in such cases as drunkenness, drug-addiction, and such-like) that due notice shall be given by either party of its intention to determine the contract, and I would suggest three months as being a reasonable period for this purpose. It is significant that the explanatory memorandum which follows the Minister's proposals in the *Supplement* of June 11 (p. 321) states that "boards will be entitled to expect reasonable notice to be given them by any officer who wishes to resign his appointment." It omits all reference to the equal entitlement on the part of the officer to expect reasonable notice of the board's wish to terminate his appointment. Some wording in the exchange of letters is essential to secure the establishment of this right.

Time probably does not permit any centrally directed action from Tavistock Square. Previous experience of the non-militancy of the central hierarchy of the B.M.A. fails to reveal any spirit which would direct such action even if time did permit. It therefore rests with individual consultants to protect themselves in the manner I have suggested. But individual action is weak. Only concerted action is strong. Let, therefore, every hospital staff throughout the country meet to discuss this. Let groups of staffs agree whether or not the points I have brought to light are worth insisting upon. If groups of hospitals covering wide areas act together, and if sufficient such areas act in similar vein, then we must inevitably bring the Minister to realize that a contract is not only a bilateral thing, but also that he is a buyer and we are the sellers, and we hold the market.

We have the additional advantage that he is not the only buyer. We can sell either to him (and through him to the ultimate consumer—the patient), or we can sell to the consumer direct. If he wants to corner the market let him realize that he can do so only by buying on our terms. It is simple commerce.

Lastly, let us not forget that we did not invite the Minister to assume the role of the medical middleman. It is a self-assumed role, and it is for him to succeed or fail on his own merits—not on ours. But if he is not the only buyer for our wares, we are most emphatically the only seller from whom he can seek that which he must have, which he must buy—viz., the professional skill, experience, and knowledge necessary for the operation of the hospital services of the National Health Service. The future of the specialists is therefore in their own hands. Are they going to throw it away?—I am, etc.,

Penzance, Cornwall.

GEOFFREY MYERS.

Supply of Cars

SIR,—I have been instructed by the East Yorkshire Branch Council to write to you regarding the results obtained in East Yorkshire from an inquiry into the delivery of new cars to doctors. A questionnaire was sent to all members, and so far 114 replies have been received, some half-dozen replies being in duplicate, covering assistants' cars, so that, taking into consideration retired doctors and men not essentially requiring cars, there has been a response indicative of the interest in the matter.

Briefly, the results are as follows:

(1) 76 doctors state that they possess post-war cars. Of these 76, no fewer than 12 state quite unprompted that they have only recently received delivery after a wait of several years, while five doctors wish to comment favourably on their treatment by distributors.

(2) 38 doctors possess unsuitable cars (with a few exceptions pre-war models) and have had others on order for varying periods (three months to three years) without delivery.

Of these 38, 17 have been supported by a B.M.A. letter of recommendation; of these 17, all but two possess pre-war cars, with the lowest mileage 46,000 and the highest 250,000. Several are using borrowed cars. A similar state of affairs holds good for the remaining 21 who have not appealed for help, some of whom state that their cars are on their last legs.

It is difficult to give an impression of the results without perusal of the replies, but there is obviously widespread dissatisfaction with the state of affairs. I have received several bitter letters and more acid comments on the subject of "priority." There is, for instance, the case of a consulting surgeon here, on call in emergency to hospitals as far afield as Bridlington and Driffield (30 miles). He is running a 1936 Ford 8 with completed mileage of over 60,000. He has had a car ordered since May, 1946, has had a B.M.A. priority recommendation for over a year, and has appealed to the distributors, and I think the makers, without the slightest effect. No comment is required here.

It may be argued that in the past doctors have spoiled their own priority, but this can only apply to men not in the Forces during the war—and not to all of them surely—and that those demobilized after January, 1946, were left at the mercy of the second-hand market or in the hands of a sympathetic dealer.—I am, etc.,

W. M. GIBSON,
East Yorks Branch Council.

SIR,—Dr. R. S. Nicholson's letter (*Supplement*, May 14, p. 272) prompts me to relate my own experience.

My old car had done 83,000 miles in ten years and was fast wearing out in spite of heavy repair bills. My new car, ordered in December, 1946, was not even in sight. In November, 1948, I wrote to the B.M.A. giving all required particulars duly certified, and I was shortly informed by a motor firm that as my name was on the B.M.A. sponsored list they would do their best to expedite delivery.

On April 8 I took delivery of the first of a certain type of car to be seen in the county; the main agents had not even had one for demonstration. Naturally I was sincere in my thanks to the B.M.A. and to the firm for their help and consideration.—I am, etc.,

Willington, Sussex.

E. VENN CLAYDON.

Supplementary Ophthalmic Service

SIR,—I was very pleased to read Dr. James H. Mellotte's letter (*Supplement*, March 26, p. 167). It is of considerable importance, for two definite factions are rapidly developing among ophthalmologists. There is the small but influential group who are entrenched in hospital appointments—often multiple—and who have long held monopolies over large populations and seek to maintain them. They appear to regard the Supplementary Service as a menace to their private practices and are seeking to discredit it. Where they have centres they are able to create waiting-lists, some of the people on which may be expected to tire of waiting and to make private appointments.

On the other hand, the younger men in practice, the general-practitioner ophthalmologists as well as whole-time ophthalmologists who have not got hospital appointments, welcomed

the Supplementary Service. I have seen the necessity for security and independence which they have to have. Each side is tending to regard the other as the sort of thing which, and as the divergent points being more marked. I have split into bitterly opposed camps. I have developed. This is the time when it is or by the time we have had results, but action must be taken. I full read for the facts mentioned—I am, etc.

Liberton, Wrexham.

J. T. WASH

Fees for Vaccination and Immunization

Sir,—In view of the complete lack of action in the negotiations on payment for the service, the fact that no fees for them have been received since Jan. 1, 1948, the Norfolk Local Medical Committee has recommended all doctors in its area to continue these services but to retain the record cards and not send them in to the local health authority until a satisfactory agreement has been reached. The committee hopes that other local medical committees will take similar action in this matter. I am, etc.

JOHN SAWELL
Hon. Secretary
Norfolk Local Medical Committee

Hospital Registrars

Sir,—The grading of the hospital registrars with the concurrent modifications in establishments is obviously necessary and inevitable, but if it is to take effect all over the country at a more or less synchronous date (as it appears it will) a large-scale "general post" must occur, with considerable transient unemployment.

As a whole the registrar group have but the smallest margin between income and inescapable expenditure (a large proportion being ex-Service, married, and with families) and even short periods of unemployment prove very heavy.

The Association, in its negotiations, could greatly ease our position if it would arrange for the change over to be staggered in all hospitals throughout a region over a period of several months. The prolongation of the ex-Service training scheme, which in some areas is being very suddenly withdrawn, would also form an invaluable buffer against a hardship which with thoughtful and unhurried organization need not prove inevitable.—I am, etc.

Topsvich

NICOLAS MALLISON

Assistantships

Sir,—Half the world does not know how the other half lives. It is true of the medical profession. As one who has lately finished with the slavery of "assistantship" I can well understand the views and growing volume of protests—almost mounting to revolutionary agitation for emancipation—from this underprivileged class of our profession.

Assistant, 'Fiat Lux,' etc., have done their utmost to direct the searchlight on this unhappy state. Let the 'Big Berthas' of the profession, whose roars alone over the years have dominated the whole scene, consider the working conditions of the assistants.

It seems to me that A B C (*Supplement*, May 28, p. 300) was in that very small class who served their assistantship under practising Christian principals or close relations. To state that 'I know of no principal who pays less than £750 plus house and often a car allowance' is proof of his ignorance of how other principals behave. Please permit me, Sir, to state a few facts for his benefit.

Early in the last war my close friend qualified. He answered an advertisement for £350 all found and car provided. After he interviewed the salary became £300. His circumstances forced him to take it, but he left after six months.

I qualified after him. I was rejected for the Services. It was a year before I obtained a post. My prospective principal was a squadron leader. He informed me that his practice was fairly large and included Post Office Public Assistance, Labour Exchange, and National Fire Service appointments, along with part of another doctor's practice who was in the Service. He asked what I wanted. With the knowledge of my friend's earlier experience and my own financial position then I

cautiously plumped for £400 inclusive of everything. He offered me £200 all found, and car provided. Coupled with this were the most encouraging remarks to carry on the practice.

I would mine and not to overwork. Most reluctantly, and for personal reasons unconnected with the relationship, which was good, I had to leave. My relationship with his patients was very happy and he has since written to thank me again for my services during the war. We parted on the best of terms. He offered me his services if ever I needed them for my advancement.

Next I obtained an assistantship on exactly the same terms. My principal's wife was a model of a hostess. The whole environment in the home was conducive to happiness, and I settled down happily. Night work was one in four months. Occasion arose when he started to violate the terms of our agreement. I took two independent legal opinions on the matter before I called his attention to the fact. For this impertinence I got the sack.

Shortly afterwards I got another assistantship at very slightly higher pay. I held this for over four years. Here, although I had been used to hard work, I had to work harder still. There were numerous night calls, and visits averaged for the whole year around 20-25 a day, seven days a week, except my holidays. Patients arrived at 7.30 a.m. and 3.30 p.m. for 9 a.m. and 5 p.m. surgeries respectively. Long and arduous hours were put in and at the end of the day one was mentally and physically exhausted. I had been there over two years when the increased capitation fee was made retrospective, and he netted £1,000 clear. Not a penny was offered me.

After four years' service, when the appointed day was looming large on the horizon, he magnanimously proposed sale of partnership. He was anxious to get things settled before July 5, 1948, and prevent anyone else coming into the area. Thus it was merely business and not in recognition of service. Although I had one increment over those years, I never came up to the ideal of "A B C." The practice was over 7,000 and the income was nearly £5,000. I declined the offer. Fairly enough, he admitted the increase in practice since I went there. In fairness to him also I ought to mention that he worked very hard. It must have been a shock to "A B C" to hear from their new partner the opinion of assistants of the principals. The assistant's remedy as he proposed is not as clear as all that.

In the different industries the unions, especially since the war, have done so much for the protection of their members. The sceptre of strike so often used is not available to the doctors. May we entertain the fervent hope that with these exposures those "haves" will henceforth behave decently to the "have nots"? It is not envy but elementary justice that is called for.

Concluding, Sir, may I plead with the B.M.A. indirectly to protect the assistants and locums looking for work through the Bureau? By requesting principals to supply the certified number of patients on their lists the prospective employee doctor will be able to judge for himself what he is in for.—I am, etc.,

EX ASSISTANT

National Service Officers

Sir,—It was with considerable interest that we read in the Supplementary Annual Report of the Council of the B.M.A. (*Supplement*, May 28, p. 293) that the Council has taken up with the Ministry of Defence and Service Departments the fact that the increased marriage allowances paid to serving officers does not apply to national service officers called up after Jan. 1, 1947. We feel that this gross example of discrimination should be more widely known.

Surely the increased cost of living is felt by all members of the community, perhaps most of all by the young newly wed and those with young children, who in many cases are having to live in accommodation grossly inadequate at what one can only call exploited rentals. And yet these, we are the people who are not to benefit.

It would be interesting to know just how many officers are affected by this refusal of the extra 6s. a day (taxable) or rather how much the Exchequer benefits by it, also just what number of married national service officers over the age of 25 there are in corps other than the R.A.M.C. We are

and while we appreciate the efforts of the Council on our behalf we deplore the apparent apathy on this matter among our fellow officers of the corps.—I am, etc.,

JOHN H. H. OLIVER,
Lieut., R.A.M.C.

K. E. JEFFERSON,
Capt., R.A.M.C.

Locally Recruited C.M.S. Officers

SIR.—Dr. Oladele A. Ajose (*Supplement*, June 4, p. 310) suggests equal pay for officers of the Colonial Medical Service, whether patriate or expatriate. This I agree with, provided the salaries are in relation to the economics of the Colony concerned.

Present basic salaries in most cases are as much as the individual Colonies will be able to afford when health and welfare services are fully developed. However, no European medical officers could be recruited on the basic salary alone, and would require their salaries to be made up by expatriation allowances. But these allowances should be paid by the Colonial Office from United Kingdom funds under the Colonial Development and Welfare Acts, and have nothing to do with the finances of the individual Colonies. This would avoid locally recruited officers complaining that Europeans are paid more by the Colonies than they are, and might help to unify the Colonial Medical Service.

Incidentally, how many locally recruited medical officers belong to the Colonial Medical Service? Most of them, I believe, are not liable to transfer outside the Colony in which they have been recruited, and therefore are not part of the unified service.—I am, etc

ANNUAL MEETING POST OFFICE

For the British Medical Association's meeting at the Royal Hall, Harrogate, Yorkshire, from June 24 to July 1, the G.P.O. has provided a temporary post office in the Royal Hall Annexe for the sale of stamps and postal orders, and acceptance of telegrams, registered letters, and parcels. Nine exchange lines fitted with multi-coin boxes have been installed for the delegates.

27 Wed. Committee on the Postgraduate Education of General Practitioners, 2 p.m.

Branch and Division Meetings to be Held

MID-ESSEX DIVISION.—At Chelmsford and Essex Hospital, Sunday, July 3, 10 a.m. Mr. M. D. Sheppard: "Urinary Obstruction and the Significance of Haematuria."

Meetings of Branches and Divisions

METROPOLITAN COUNTIES BRANCH

The 91st annual general meeting of the Metropolitan Counties Branch was held at Association House, London, on June 7. Mr. A. M. A. Moore, the retiring president, was in the chair during the first part of the meeting, and was followed by Dr. C. G. Martin.

The report of the Branch Council showed that the membership of the Branch was 7,396, an increase of 463 on the year. The report, with the financial statement, and the report of the Branch representatives on the Central Council were received and adopted.

The following nominations were accepted for 1949-50: president-elect, Dr. Frank Gray; vice-presidents, Miss Beatrice-Turner, Dr. A. E. French, Dr. A. Ricketts, and Dr. J. B. Mason, with Dr. J. W. McCarthy and Dr. A. H. Weston as hon. secretaries, and Dr. D. F. Hutchinson as treasurer.

Dr. C. G. Martin, president of the Branch, was then inducted and delivered an interesting address on the Port of London. He traced the history of the port from the earliest times, the great commercial development of the sixteenth and seventeenth centuries, the opening of the first docks (in the modern sense of the term) at the beginning of the nineteenth century, and the advent, in 1908, of the Port of London Authority. The present-day Port of London comprised the tidal Thames from Teddington to the Nore—60 miles of busy waterway—an estate of more than 4,000 acres, and nearly 45 miles of deep-sea quays for berthing ocean-going vessels. The Port of London was the second passenger port of the United Kingdom. He also touched on the war story of the port and the formation of the river emergency service of motor launches and river hospital ships manned by volunteers, with a staff of doctors and nurses, to deal with riverside casualties. Finally, he remarked on the medical side of the port work, including the examination of employees and the training of first-aid personnel. The health conditions on in-coming ships were watched by the Port of London Health Department—a department of the City Corporation. Vessels were boarded at Gravesend according to the reports which they telegraphed to this health authority before entering the river. In 1947, out of 6,850 vessels arriving from foreign ports, 1,503 were boarded; 183 cases of communicable diseases were reported on 125 of the vessels during the voyage, and of this number 96 were landed in the port.

In order that vessels on foreign service might be boarded and inspected when necessary, the master of the vessel approaching the port must ascertain the health of all persons on board and fill in and sign a declaration of health. If the vessel had come from ports in Asia or Central or South America or a number of other places the master must send a wireless message stating the time he would arrive off Gravesend, or, if he had no wireless, he must report to the North Foreland, and would then be boarded.

Dr. Martin was warmly thanked for his address. He stated that if a suitable number of members of the Branch formed a party the Port of London Authority would place their yacht *St. Katherine* at the party's disposal for a tour of the Royal Docks as their guests.

Correction

In the map of N. Ireland (*Supplement*, June 18, p. 334) Co. Armagh was mistakenly labelled Co. Monaghan.

INDEX TO VOLUME I FOR 1949

READERS in search of a particular subject will find it useful to bear in mind that the references are in several cases distributed under two or more separate headings—for example Brain and Cerebral; Heart and Cardiac; Liver and Hepatic; Renal and Kidney; Cancer and Carcinoma; Child and Infant; Gout and Thyroid. Subjects dealt with under various main headings in the JOURNAL have been set out in alphabetical order under their respective headings—for example, "Annotations," "Correspondence," "Leading Articles," "Obituary," "Reviews," etc. Original Articles are indicated by the letter (O).

 TRINICK, R. H. : Antihistamine drugs and erythroblastosis, 194
 Tropical diseases centre, 328
 TRUELOVE, Sidney (and D. C. LEWIN) : Haematemesis with special reference to chronic peptic ulcer, 383 (O); leading article, 400; correspondence, 590
 TRUETA, Joseph : *An Atlas of Traumatic Surgery*, 761—(And others) : Research in renal disease, 1007
 TRUOX, R. C. (and C. E. KELLNER) : *Detailed Atlas of the Head and Neck*, 668
 Trypanosomiasis, control of : insecticides and anticyde (D. G. Davey), 1046
 TSCHERNE, E. : *Sexual hormonotherapie*, 274
 Tssetse over Africa (leading article), 315
 TUBERCULOSIS :
 Air travel contraindication for, 605
 B.C.G., 778, 868—National trial of (leading article), 624—In Finland, 636
 Book reviews, 483, 578, 620
 Bronchopneumonia tuberculous, in childhood : Streptomycin treatment of (R. McLaren Todd), 741 (O); leading article, 764
 Chemotherapy of (Fine Chemicals Group of the Society of Chemical Industry), 232
 Children : Some practical problems of tuberculosis in childhood (P. M. B. Allen), 747 (O)
 Congenital, case of (J. W. Jordan and H. Spencer), 217 (O)
 Co-ordination of services (leading article), 226; correspondence, 321
 Cow's milk and, 955
 Diagnosis : Early diagnosis, 235, 591, 681—Delayed diagnosis, 29—Diagnosis in general practice, 778
 Exercises : Graduated, 205—Breathing, 205
 Ex-Servicemen, tuberculosis in, 421
 Family, tuberculosis in the, 365
 Heredity and pulmonary, 555
 Histology of the tuberculous lesion, 748
 Industry : Tuberculosis in industry—an epidemiological study (Alice Stewart and J. P. W. Hughes), 926 (O); leading article, 946; correspondence, 1049
 Infection : Mode of infection in infants and children, 747

TUBERCULOSIS (continued):

- Locum register for tuberculosis work, 1058
Meningitis, tuberculous. Diagnosis, 75, 195, 235
364—Early diagnosis and a review of treatment with streptomycin (J. Rubie and A. F. Mohan)
338 (O); annotation, 357; correspondence, 498, 777—Treatment with streptomycin (Scotland), 628
Mortality, 209, 210
Necropses and tuberculous infection (annotation), 907
Para-aminosalicylic acid in (annotation) 190
Pneumothorax, artificial: Self administered refills 113—Place of, in treatment of pulmonary tuberculosis s, 319
Pregnancy and, 1047
Pulmonary complicated by amoebic hepatitis (A. Erdel), 18
Septicaemic, with agranulocytosis (a new syndrome) 407
Spread by books, 601, 832, 1062
Statistics: Ministry statement, 493
Streptomycin: Report of subcommittee of the Standing Advisory Committee on Tuberculosis 260—Annotation on, 907
Tuberculosis at the crossroads (C. O. Stallybrass) 207 (O); leading article, 226, correspondence 321, 365
Vaccination 211
Whither tuberculosis? 70, 152, 365, 412, 593, 634, 777
X-ray examinations in Switzerland 943

- Tumours: Review of book on diagnosis of 19—Melanin forming epidermal 407—Contraindication to air travel, 605. See also Cancer
TURNER, C. Donnell: General Endocrinology 901
—E. A. (and G. Foster): Skull closure by acrylic plates, 619
—G. Grey: Occupational diseases of the lens and retina, 497—Perforations of oesophagus and of rectum, 1095
—Peter (and R. V. Dent): Three cases of fulminant meningococcal septicaemia with one recovery, 524 (O), correspondence 633, 681
—R. W. D.: Needle biopsy of liver 820
—W. C.: Intussusception due to carcinoma of colon, 195
TURN, J. (editor): Atomic Energy Year Book, 902
Twigg, Donald Sargenson obituary notice of 960
Twins: Ife females born co-twin with males sterile? (J. Chassard Mour), 69
Typhoid: See Fevers
